**Constraints:** $\text{is_default_constructible_v<T_i>}'$ is true for all $i$.

**Effects:** Value-initializes each element.

**Remarks:** The expression inside explicit evaluates to true if and only if $T_i$ is not copy-list-initializable from an empty list for at least one $i$.

[Note 1: This behavior can be implemented with a trait that checks whether a const $T_i '&' can be initialized with $\{}$ —end note]

```cpp
constexpr explicit(see below) tuple(const Types&...);
```

**Constraints:** sizeof...(Types) $\geq 1$ and $\text{is_copy_constructible_v<T_i>}'$ is true for all $i$.

**Effects:** Initializes each element with the value of the corresponding parameter.

**Remarks:** The expression inside explicit is equivalent to:

```cpp
!conjunction_v<is_convertible<const Types&, Types>...>
```

```cpp
template<class... UTypes> constexpr explicit(see below) tuple(UTypes&&... u);
```

**Constraints:**

- sizeof...(Types) equals sizeof...(UTypes),
- sizeof...(Types) $\geq 1$, and
- conjunction_v<disambiguating-constraint, is_constructible<Types, UTypes>...>' is true.

**Effects:** Initializes the elements in the tuple with the corresponding value in std::forward<UTypes>(u).

**Remarks:** The expression inside explicit is equivalent to:

```cpp
!conjunction_v<is_convertible<UTypes, Types>...>
```

This constructor is defined as deleted if

```cpp
(reference_constructs_from_temporary_v<Types, UTypes&&> || ...)
```

is true.

```cpp
tuple(const tuple& u) = default;
```

**Mandates:** $\text{is_copy_constructible_v<T_i>}'$ is true for all $i$.

**Effects:** Initializes each element of *this with the corresponding element of u.

```cpp
tuple(tuple&& u) = default;
```

**Constraints:** $\text{is_move_constructible_v<T_i>}'$ is true for all $i$.

**Effects:** For all $i$, initializes the $i^{\text{th}}$ element of *this with std::forward<T>(get<i>(u)).
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>&& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>&& u);

Let I be the pack 0, 1, ..., (sizeof...(Types) - 1).
Let \( FWD(u) \) be static_cast<decltype(u)>(u).

Constraints:
(21.1) sizeof...(Types) equals sizeof...(UTypes), and
(21.2) \( \text{is\_constructible}_v<Types, \text{decltype}(get<I>(FWD(u)))> \& \text{...} \) is true, and
(21.3) either sizeof...(Types) is not 1, or (when Types... expands to T and UTypes... expands to U)
\( \text{is\_convertible}_v<T, \text{decltype}(u)>, \text{is\_constructible}_v<T, \text{decltype}(u)>, \text{is\_same\_v<T, U> \text{are all false.}} \)

Effects: For all \( i \), initializes the \( i \)th element of *this with get\( <i>(FWD(u)) \).
Remarks: The expression inside explicit is equivalent to:
\(!\text{is\_convertible}_v<\text{decltype}(get<0>(FWD(u))), Types> \& \text{...} \)

The constructor is defined as deleted if
\( \text{reference\_constructs\_from\_temporary}_v<Types, \text{decltype}(get<0>(FWD(u)))> || \text{...} \)
is true.

template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>&& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>&& u);

Let \( FWD(u) \) be static_cast<decltype(u)>(u).

Constraints:
(25.1) sizeof...(Types) is 2,
(25.2) \( \text{is\_constructible}_v<T_0, \text{decltype}(get<0>(FWD(u)))> \) is true, and
(25.3) \( \text{is\_constructible}_v<T_1, \text{decltype}(get<1>(FWD(u)))> \) is true.

Effects: Initializes the first element with get\( <0>(FWD(u)) \) and the second element with get\( <1>(FWD(u)) \).
Remarks: The expression inside explicit is equivalent to:
\(!\text{is\_convertible}_v<\text{decltype}(get<0>(FWD(u))), T_0> || \text{...} \)
\(!\text{is\_convertible}_v<\text{decltype}(get<1>(FWD(u))), T_1> || \text{...} \)
The constructor is defined as deleted if
\( \text{reference\_constructs\_from\_temporary}_v<T_0, \text{decltype}(get<0>(FWD(u)))> || \text{reference\_constructs\_from\_temporary}_v<T_1, \text{decltype}(get<1>(FWD(u)))> \)
is true.

template<tuple-like UTuple>
constexpr explicit(see below) tuple(UTuple&& u);

Let I be the pack 0, 1, ..., (sizeof...(Types) - 1).

Constraints:
(29.1) different-from<UTuple, tuple> (26.5.2) is true,
(29.2) remove_cvref_t<UTuple> is not a specialization of ranges::subrange,
(29.3) sizeof...(Types) equals tuple_size_v<remove_cvref_t<UTuple>>.
(29.4) \( \text{is\_constructible}_v<T, \text{decltype}(get<I>(std::forward<UTuple>(u)))> \& \text{...} \) is true, and
(29.5) either sizeof...(Types) is not 1, or (when Types... expands to T) \( \text{is\_convertible}_v<\text{UTuple}, T> \) and \( \text{is\_constructible}_v<T, \text{UTuple}> \) are both false.
Effects: For all \(i\), initializes the \(i\)th element of \(*this\) with \(\text{get}\:<i>(\text{std::forward<UTuple>}(u))\).

Remarks: The expression inside \texttt{explicit} is equivalent to:

\[!(\text{is_convertible_v<decltype(\text{get}\:<I>(\text{std::forward<UTuple>}(u))), \text{Types}> \&\& \ldots})\]

### Examples

```cpp
template<class Alloc>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a);

template<class Alloc>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, const Types&...);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, UTypes&...);
```

Preconditions: Alloc meets the \texttt{Cpp17Allocator} requirements (16.4.4.6.1).

Effects: Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (20.2.8.2).

### Assignment

22.4.4.3 Assignment [tupl.assign]

For each \texttt{tuple} assignment operator, an exception is thrown only if the assignment of one of the types in \texttt{Types} throws an exception. In the function descriptions that follow, let \(i\) be in the range \([0, \text{sizeof...(Types)})\) in order, \(T_i\) be the \(i\)th type in \texttt{Types}, and \(U_i\) be the \(i\)th type in a template parameter pack named \texttt{UTypes}, where indexing is zero-based.

```cpp
constexpr tuple&amp; operator=(const tuple&amp; u);
```

Effects: Assigns each element of \(u\) to the corresponding element of \(*this\).

Returns: \(*\text{this}\).

Remarks: This operator is defined as deleted unless \texttt{is_copyAssignable_v<T\:<i>\&\&}} is true for all \(i\).
constexpr const tuple& operator=(const tuple& u) const;
Constraints: (is_copy_assignable_v<const Types> && ...) is true.
Effects: Assigns each element of u to the corresponding element of *this.
Returns: *this.

castexpr const tuple& operator=(tuple&& u) noexcept(see below);
Constraints: is_move_assignable_v<T_i> is true for all i.
Effects: For all i, assigns std::forward<T_i>(get<i>(u)) to get<i>(*this).
Returns: *this.

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

where T_i is the i_th type in Types.

castexpr const tuple& operator=(tuple&& u) const;
Constraints: (is_assignable_v<const Types&, Types> && ...) is true.
Effects: For all i, assigns std::forward<T_i>(get<i>(u)) to get<i>(*this).
Returns: *this.

Returns: *this.

template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);
Constraints:
(15.1) sizeof...(Types) equals sizeof...(UTypes) and
(15.2) is_assignable_v<T_i, const U_i&> is true for all i.
Effects: Assigns each element of u to the corresponding element of *this.
Returns: *this.

Returns: *this.

template<class... UTypes> constexpr const tuple& operator=(const tuple<UTypes...>& u) const;
Constraints:
(18.1) sizeof...(Types) equals sizeof...(UTypes) and
(18.2) (is_assignable_v<const Types&, const UTypes&> && ...) is true.
Effects: Assigns each element of u to the corresponding element of *this.
Returns: *this.

Returns: *this.

template<class... UTypes> constexpr tuple& operator=(tuple<UTypes...>& u);
Constraints:
(21.1) sizeof...(Types) equals sizeof...(UTypes) and
(21.2) is_assignable_v<T_i, U_i> is true for all i.
Effects: For all i, assigns std::forward<U_i>(get<i>(u)) to get<i>(*this).
Returns: *this.

Returns: *this.

template<class... UTypes> constexpr const tuple& operator=(tuple<UTypes...>& u) const;
Constraints:
(24.1) sizeof...(Types) equals sizeof...(UTypes) and
(24.2) (is_assignable_v<const Types&, UTypes> && ...) is true.
Effects: For all i, assigns std::forward<U_i>(get<i>(u)) to get<i>(*this).
Returns: *this.

Returns: *this.

template<class U1, class U2> constexpr tuple& operator=(const pair<U1, U2>& u);
Constraints:
(27.1) sizeof...(Types) is 2 and
is_assignable_v<T0&, const U1&> is true, and
— is_assignable_v<T1&, const U2&> is true.

**Effects:** Assigns `u.first` to the first element of `*this` and `u.second` to the second element of `*this`.

**Returns:** `*this`.

```cpp
template<class U1, class U2> constexpr const tuple& operator=(const pair<U1, U2>& u) const;
```

**Constraints:**
— sizeof...(Types) is 2,
— is_assignable_v<const T0&, const U1&> is true, and
— is_assignable_v<const T1&, const U2&> is true.

**Effects:** Assigns `u.first` to the first element and `u.second` to the second element.

**Returns:** `*this`.

```cpp
template<class U1, class U2> constexpr tuple& operator=(pair<U1, U2>&& u);
```

**Constraints:**
— sizeof...(Types) is 2 and
— is_assignable_v<T0&, U1> is true, and
— is_assignable_v<T1&, U2> is true.

**Effects:** Assigns `std::forward<U1>(u.first)` to the first element of `*this` and `std::forward<U2>(u.second)` to the second element of `*this`.

**Returns:** `*this`.

```cpp
template<class U1, class U2> constexpr const tuple& operator=(pair<U1, U2>&& u) const;
```

**Constraints:**
— different-from<UTuple, tuple> (26.5.2) is true,
— remove_cvref_t<UTuple> is not a specialization of ranges::subrange,
— sizeof...(Types) equals tuple_size_v<remove_cvref_t<UTuple>>, and,
— is_assignable_v<T&, decltype(get<i>(std::forward<UTuple>(u)))) is true for all `i`.

**Effects:** For all `i`, assigns `get<i>(std::forward<UTuple>(u))` to `get<i>(*this)`.

**Returns:** `*this`.

```cpp
template<tuple-like UTuple>
constexpr tuple& operator=(UTuple&& u);
```

**Constraints:**
— different-from<UTuple, tuple> (26.5.2) is true,
— remove_cvref_t<UTuple> is not a specialization of ranges::subrange,
— sizeof...(Types) equals tuple_size_v<remove_cvref_t<UTuple>>, and,
— is_assignable_v<const T&, decltype(get<i>(std::forward<UTuple>(u)))) is true for all `i`.

**§ 22.4.4.3**
Effects: For all \( i \), assigns \( \text{get}<i>(\text{std::forward}<\text{UTuple}>(u)) \) to \( \text{get}<i>(\ast\text{this}) \).

Returns: \( \ast\text{this} \).

22.4.4.4 swap

```
constexpr void swap(tuple& rhs) noexcept(see below);
constexpr void swap(const tuple& rhs) const noexcept(see below);
```

Let \( i \) be in the range \([0, \text{sizeof...}(\text{Types}))\) in order.

Mandates:
1. For the first overload, \((\text{is_swappable}_v\langle\text{Types} \& \& \ldots \rangle)\) is true.
2. For the second overload, \((\text{is_swappable}_v\langle\text{const Types} \& \& \ldots \rangle)\) is true.

Preconditions: For all \( i \), \( \text{get}<i>(\ast\text{this}) \) is swappable with \((16.4.4.3) \text{get}<i>(\text{rhs})\).

Effects: For each \( i \), calls \( \text{swap} \) for \( \text{get}<i>(\ast\text{this}) \) and \( \text{get}<i>(\text{rhs}) \).

Throws: Nothing unless one of the element-wise \( \text{swap} \) calls throws an exception.

Remarks: The exception specification is equivalent to
1. \((\text{is_nothrow_swappable}_v\langle\text{Types} \& \& \ldots \rangle)\) for the first overload and
2. \((\text{is_nothrow_swappable}_v\langle\text{const Types} \& \& \ldots \rangle)\) for the second overload.

22.4.5 Tuple creation functions

```
template<class... TTypes>
constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);
```

Returns: \( \text{tuple}<\text{unwrap_ref_decay_t}<\text{TTypes}...\rangle\)(std::forward<TTypes>(t)...).

Example 1:

```
int i; float j;
make_tuple(1, ref(i), cref(j));
```

creates a tuple of type \( \text{tuple<int, int&, const float&}> \).

Template:
```
template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;
```

Effects: Constructs a tuple of references to the arguments in \( t \) suitable for forwarding as arguments to a function. Because the result may contain references to temporary objects, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

Returns: \( \text{tuple<TTypes&&...>(std::forward<TTypes>(t)...).} \)

Example 2: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for elements that are not needed:

```
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

Template:
```
template<tuple-like... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);`
Let $S_i$ be \( \text{tuple\_size\_v}\langle U_i, \rangle \).

Let $E_k^i$ be \( \text{tuple\_element\_t}<k, U_i, \rangle \).

Let $e_k^i$ be \( \text{get}<k>(\text{std::forward}<T,>(\text{tp}_i)) \).

Let $Elems_i$ be a pack of the types $E_0^i, \ldots, E_{S_i-1}^i$.

Let $elems_i$ be a pack of the expressions $e_0^i, \ldots, e_{S_i-1}^i$.

The types in $\text{CTypes}$ are equal to the ordered sequence of the expanded packs of types $Elems_0, \ldots, Elems_1, \ldots, Elems_{n-1}$. Let $\text{celems}$ be the ordered sequence of the expanded packs of expressions $elems_0, \ldots, elems_{n-1}$.

Mandates: $(\text{is\_constructible\_v}\langle \text{CTypes}, \text{decltype}(\text{celems}) \rangle \&\& \ldots)$ is true.

Returns: \( \text{tuple}\langle \text{CTypes} \ldots \rangle(\text{celems} \ldots) \).

### 22.4.6 Calling a function with a tuple of arguments

```cpp
template<class F, tuple-like Tuple>
constexpr decltype(auto) apply(F&& f, Tuple& t) noexcept;
```

Effects: Given the exposition-only function template:

```cpp
namespace std {
    template<class F, tuple-like Tuple, size_t... I>
    constexpr decltype(auto) apply-impl(F&& f, Tuple& t, index_sequence<I...>) {
        // exposition only
        return INVOKE(std::forward<F>(f), get<I>(std::forward<Tuple>(t)))...;  // see 22.10.4
    }
}
```

Equivalent to:

```cpp
return apply-impl(std::forward<F>(f), std::forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

Remarks: Let $I$ be the pack $0, 1, \ldots, (\text{tuple\_size\_v}<\text{remove\_reference\_t}<\text{Tuple}>> - 1)$. The exception specification is equivalent to:

```cpp
noexcept(invoke(std::forward<F>(f), get<I>(std::forward<Tuple>(t)))\ldots))
```

```cpp
template<class T, tuple-like Tuple>
constexpr T make_from_tuple(Tuple& t);
```

Mandates: If $\text{tuple\_size\_v}<\text{remove\_reference\_t}<\text{Tuple}>>$ is 1, then $\text{reference\_constructs\_from\_-temporary\_v<T, \text{decltype}(get<0>(\text{declval}<\text{Tuple}>(}))>$ is false.

Effects: Given the exposition-only function template:

```cpp
namespace std {
    template<class T, tuple-like Tuple, size_t... I>
    requires is_constructible_v<T, decltype(get<0>(declval<Tuple>()))...>
    constexpr T make-from-tuple-impl(Tuple& t, index_sequence<I...>) {
        // exposition only
        return T(get<I>(std::forward<Tuple>(t)))...;
    }
}
```

Equivalent to:

```cpp
return make-from-tuple-impl<T>(
    std::forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

Note 1: The type of $T$ must be supplied as an explicit template parameter, as it cannot be deduced from the argument list. — end note

### 22.4.7 Tuple helper classes

```cpp
template<class T> struct tuple_size;
```

All specializations of $\text{tuple\_size}$ meet the $\text{Cpp17UnaryTypeTrait}$ requirements (21.3.2) with a base characteristic of $\text{integral\_constant}<\text{size}_t, N>$ for some $N$. 

§ 22.4.7 714
template<class... Types>
struct tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { };

template<size_t I, class... Types>
struct tuple_element<I, tuple<Types...>> {
  using type = TI;
};

Mandates: I < sizeof...(Types).

Type: TI is the type of the I^{th} element of Types, where indexing is zero-based.

template<class T> struct tuple_size<const T>;

Let TS denote tuple_size<T> of the cv-unqualified type T. If the expression TS::value is well-formed
when treated as an unevaluated operand (7.2.3), then each specialization of the template meets the
Cpp17UnaryTypeTrait requirements (21.3.2) with a base characteristic of
integral_constant<size_t, TS::value>
Otherwise, it has no member value.

Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate
context of the expression is considered.

[Note 1: The compilation of the expression can result in side effects such as the instantiation of class template
specializations and function template specializations, the generation of implicitly-defined functions, and so on.
Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end
note]

In addition to being available via inclusion of the <tuple> header, the template is available when any
of the headers <array> (24.3.2), <ranges> (26.2), or <utility> (22.2.1) are included.

template<size_t I, class T> struct tuple_element<I, const T>;

Let TE denote tuple_element_t<I, T> of the cv-unqualified type T. Then each specialization of the
template meets the Cpp17TransformationTrait requirements (21.3.2) with a member typedef

type
names the type add_const_t<TE>.

In addition to being available via inclusion of the <tuple> header, the template is available when any
of the headers <array> (24.3.2), <ranges> (26.2), or <utility> (22.2.1) are included.

22.4.8 Element access [tuple.elem]

template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&
get(tuple<Types...>& t) noexcept;

template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&&
get(tuple<Types...>&& t) noexcept;

// Note A

template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&
get(const tuple<Types...>& t) noexcept;

// Note B

template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&&
get(const tuple<Types...>&& t) noexcept;

Mandates: I < sizeof...(Types).

Returns: A reference to the I^{th} element of t, where indexing is zero-based.

[Note 1: [Note A] If a type T in Types is some reference type X&, the return type is X&, not X&&. However, if the
element type is a non-reference type T, the return type is T&&. — end note]

[Note 2: [Note B] Constness is shallow. If a type T in Types is some reference type X&, the return type is X&,
not const X&. However, if the element type is a non-reference type T, the return type is const T&. This is
consistent with how constness is defined to work for non-static data members of reference type. — end note]
template<class T, class... Types>
constexpr const T& get(const tuple<Types...>& t) noexcept;

template<class T, class... Types>
constexpr const T&& get(const tuple<Types...>&& t) noexcept;

Mandates: The type T occurs exactly once in Types.

Returns: A reference to the element of t corresponding to the type T in Types.

[Example 1:]
const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t);  // OK, i1 has value 1
const int& i2 = get<const int>(t);  // OK, i2 has value 2
const double& d = get<double>(t);  // error: type double is not unique within t
—end example]

[Note 3: The reason get is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the template keyword. —end note]

22.4.9 Relational operators [tuple.rel]

template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

template<class... TTypes, tuple-like UTuple>
constexpr bool operator==(const tuple<TTypes...>& t, const UTuple& u);

For the first overload let UTuple be tuple<UTypes...>.

Mandates: For all i, where 0 ≤ i < sizeof...(TTypes), get<i>(t) == get<i>(u) is a valid expression. sizeof...(TTypes) equals tuple_size_v<UTuple>.

Preconditions: For all i, decltype(get<i>(t) == get<i>(u)) models boolean-testable.

Returns: true if get<i>(t) == get<i>(u) for all i, otherwise false.

[Note 1: If sizeof...(TTypes) equals zero, returns true. —end note]

Remarks: (5.1) The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to false.

(5.2) The second overload is to be found via argument-dependent lookup (6.5.4) only.

template<class... TTypes, class... UTypes>
constexpr common_comparison_category_t<
synth-three-way-result<TTypes, UTypes>>...>
operator<=>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

template<class... TTypes, tuple-like UTuple>
constexpr common_comparison_category_t<
synth-three-way-result<TTypes, Elems>>...>
operator<=>(const tuple<TTypes...>& t, const UTuple& u);

For the second overload, Elems denotes the pack of types tuple_element_t<0, UTuple>, tuple_element_t<1, UTuple>, ..., tuple_element_t<tuple_size_v<UTuple> - 1, UTuple>.

Effects: Performs a lexicographical comparison between t and u. If sizeof...(TTypes) equals zero, returns strong_ordering::equal. Otherwise, equivalent to:

if (auto c = synth-three-way(get<0>(t), get<0>(u)); c != 0) return c;
return t_tail <=> u_tail;

where r_tail for some r is a tuple containing all but the first element of r.

Remarks: The second overload is to be found via argument-dependent lookup (6.5.4) only.

[Note 2: The above definition does not require t_tail (or u_tail) to be constructed. It might not even be possible, as t and u are not required to be copy constructible. Also, all comparison operator functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. — end note]

22.4.10 common_reference related specializations [tuple.common.ref]

In the descriptions that follow:
Let \( T\text{Types} \) be a pack formed by the sequence of \( \text{tuple_element_t}<i, T\text{Tuple}> \) for every integer \( 0 \leq i < \text{tuple_size_v}<T\text{Tuple}> \).

Let \( U\text{Types} \) be a pack formed by the sequence of \( \text{tuple_element_t}<i, U\text{Tuple}> \) for every integer \( 0 \leq i < \text{tuple_size_v}<U\text{Tuple}> \).

```
template<tuple-like TTuple, tuple-like UTuple, 
        template<class> class TQual, template<class> class UQual> 
struct basic_common_reference<TTuple, UTuple, TQual, UQual> { 
    using type = see below;
};
```

Constraints:

1. \( T\text{Tuple} \) is a specialization of \( \text{tuple} \) or \( U\text{Tuple} \) is a specialization of \( \text{tuple} \).
2. \( \text{is_same_v}<TTuple, \text{decay_t}<TTuple>> \) is true.
3. \( \text{is_same_v}<UTuple, \text{decay_t}<UTuple>> \) is true.
4. \( \text{tuple_size_v}<TTuple> \) equals \( \text{tuple_size_v}<UTuple> \).
5. \( \text{tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>} \) denotes a type.

The member typedef-name \( \text{type} \) denotes the type \( \text{tuple}<\text{common_reference_t<TQual<TTypes>, UQual<UTypes>>...}> \).

```
template<tuple-like TTuple, tuple-like UTuple> 
struct common_type<TTuple, UTuple> { 
    using type = see below;
};
```

Constraints:

1. \( T\text{Tuple} \) is a specialization of \( \text{tuple} \) or \( U\text{Tuple} \) is a specialization of \( \text{tuple} \).
2. \( \text{is_same_v}<TTuple, \text{decay_t}<TTuple>> \) is true.
3. \( \text{is_same_v}<UTuple, \text{decay_t}<UTuple>> \) is true.
4. \( \text{tuple_size_v}<TTuple> \) equals \( \text{tuple_size_v}<UTuple> \).
5. \( \text{tuple<common_type_t<TTypes, UTypes>>...} \) denotes a type.

The member typedef-name \( \text{type} \) denotes the type \( \text{tuple}<\text{common_type_t<TTypes, UTypes>>...}> \).

### 22.4.11 Tuple traits

```
template<class... Types, class Alloc> 
struct uses_allocator<tuple<Types...>, Alloc> : true_type { 
};
```

**Preconditions:** Alloc meets the \( \text{Cpp17Allocator} \) requirements (16.4.4.6.1).

[Note 1: Specialization of this trait informs other library components that \( \text{tuple} \) can be constructed with an allocator, even though it does not have a nested allocator_type. — end note]

### 22.4.12 Tuple specialized algorithms

```
template<class... Types> 
constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below); 
template<class... Types> 
constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept(see below);
```

**Constraints:**

1. For the first overload, \( \text{is_swappable_v}<\text{Types}>> \times \) is true.
2. For the second overload, \( \text{is_swappable_v}<\text{const Types}>> \times \) is true.

**Effects:** As if by \( x.\text{swap}(y) \).

**Remarks:** The exception specification is equivalent to:

\[
\text{noexcept}(x.\text{swap}(y))
\]
22.5 Optional objects

22.5.1 In general

Subclause 22.5 describes class template `optional` that represents optional objects. An optional object is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

22.5.2 Header `<optional>` synopsis

```cpp
// mostly freestanding
#include <compare>
// see 17.11.1
namespace std {
    // 22.5.3, class template optional
    template<class T>
    class optional; // partially freestanding
    template<class T>
    concept is-derived-from-optional = requires(const T& t) {
        []<class U>(const optional<U>&) {}(t);
    };
    // 22.5.4, no-value state indicator
    struct nullopt_t{see below};
    inline constexpr nullopt_t nullopt(unspecified);
    // 22.5.5, class bad_optional_access
    class bad_optional_access;
    // 22.5.6, relational operators
    template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);  
    template<class T, class U>
    constexpr compare_three_way_result_t<T, U> 
    operator<=>(const optional<T>&, const optional<U>&);
    // 22.5.7, comparison with nullopt
    template<class T>  
    constexpr bool operator==(const optional<T>&, nullopt_t) noexcept; 
    template<class T>
    constexpr strong_ordering operator<=>(const optional<T>&, nullopt_t) noexcept;
    // 22.5.8, comparison with T
    template<class T, class U>
    constexpr bool operator==(const optional<T>&, const U&);  
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const U&);  
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const U&);  
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const U&);  
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const U&);  
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const U&);  
}
```

§ 22.5.2 718
template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);

// 22.5.9, specialized algorithms
template<class T>
constexpr void swap(optional<T>&, optional<T>&) noexcept(see below);

template<class T>
constexpr optional<see below> make_optional(T&&);
template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);
template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// 22.5.10, hash support
template<class T> struct hash;

22.5.3 Class template optional

22.5.3.1 General

namespace std {
    template<class T>
    class optional {
    public:
        using value_type = T;

        // 22.5.3.2, constructors
        constexpr optional() noexcept;
        constexpr optional(nullopt_t) noexcept;
        constexpr optional(const optional&);
        template<class... Args>
        constexpr explicit optional(in_place_t, Args&&...);
        template<class U, class... Args>
        constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
        template<class U = T>
        constexpr explicit(see below) optional(U&&);
        template<class U>
        constexpr explicit(see below) optional(const optional<U>&);
        template<class U> constexpr explicit(see below) optional(optional<U>&&);

        // 22.5.3.3, destructor
        constexpr ~optional();

        // 22.5.3.4, assignment
        constexpr optional& operator=(nullopt_t) noexcept;
        constexpr optional& operator=(const optional&);
        template<class U = T> constexpr optional& operator=(U&&);
        template<class U> constexpr optional& operator=(optional<U>&&);
        template<class... Args> constexpr T& emplace(Args&&...);
        template<class U, class... Args> constexpr T& emplace(initializer_list<U>, Args&&...);

        // 22.5.3.5, swap
        constexpr void swap(optional&) noexcept(see below);
    }  
} // namespace std

§ 22.5.3.1 719
// 22.5.3.6, observers
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const &;
constexpr T& value() &;  // freestanding-deleted
constexpr T&& value() &&;  // freestanding-deleted
constexpr const T&& value() const &&;  // freestanding-deleted

template<class U> constexpr T value_or(U&&) const &;
template<class U> constexpr T value_or(U&&) &&;

// 22.5.3.7, monadic operations
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;

// 22.5.3.8, modifiers
constexpr void reset() noexcept;
private:
    T *val;  // exposition only
};

template<class T>
optional(T) -> optional<T>;

1 Any instance of optional<T> at any given time either contains a value or does not contain a value. When an instance of optional<T> contains a value, referred to as the optional object’s contained value, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. When an object of type optional<T> is contextually converted to bool, the conversion returns true if the object contains a value; otherwise the conversion returns false.

2 When an optional<T> object contains a value, member val points to the contained value.

3 T shall be a type other than cv in_place_t or cv nullopt_t that meets the Cpp17Destructible requirements (Table 35).

22.5.3.2 Constructors [optional.ctor]
The exposition-only variable template converts-from-any-cvref is used by some constructors for optional.

template<class T, class W>
constexpr bool converts-from-any-cvref = // exposition only
disjunction_v<
    is_constructible<T, W&>, is_convertible<W&, T>,
    is_constructible<T, W>, is_convertible<W, T>,
    is_constructible<T, const W&>, is_convertible<
        const W&, T>,
    is_constructible<T, const W>, is_convertible<
        const W, T>>;

constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;

2 Postconditions: *this does not contain a value.
**Remarks:** No contained value is initialized. For every object type `T` these constructors are constexpr constructors (9.2.6).

```cpp
constexpr optional(const optional& rhs);
```

**Effects:** If `rhs` contains a value, direct-non-list-initializes the contained value with `*rhs`.

**Postconditions:** `rhs.has_value() == this->has_value()`.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** This constructor is defined as deleted unless `is_copy_constructible_v<T>` is true. If `is_trivially_copy_constructible_v<T>` is true, this constructor is trivial.

```cpp
constexpr optional(optional&& rhs) noexcept;
```

**Effects:** If `rhs` contains a value, direct-non-list-initializes the contained value with `std::move(*rhs)`.

**Postconditions:** `rhs.has_value() == this->has_value()`.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** The exception specification is equivalent to `is_nothrow_move_constructible_v<T>`. If `is_trivially_move_constructible_v<T>` is true, this constructor is trivial.

```cpp
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

**Constraints:** `is_constructible_v<T, Args...>` is true.

**Effects:** Direct-non-list-initializes the contained value with `std::forward<Args>(args)....`

**Postconditions:** `*this` contains a value.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** If `T`'s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```cpp
template<class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);
```

**Constraints:** `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

**Effects:** Direct-non-list-initializes the contained value with `il, std::forward<Args>(args)....`

**Postconditions:** `*this` contains a value.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** If `T`'s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

```cpp
template<class U = T> constexpr explicit(U&& v);
```

**Constraints:**

(23.1) `is_constructible_v<T, U> is true`,
(23.2) `is_same_v<remove_cvref_t<U>, in_place_t> is false`,
(23.3) `is_same_v<remove_cvref_t<U>, optional> is false`, and
(23.4) if `T` is `cv bool`, `remove_cvref_t<U>` is not a specialization of `optional`.

**Effects:** Direct-non-list-initializes the contained value with `std::forward<U>(v)`.

**Postconditions:** `*this` contains a value.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** If `T`'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor. The expression inside `explicit` is equivalent to:

```cpp
!is_convertible_v<U, T>
```
template<class U> constexpr explicit(see below) optional(const optional<U>& rhs);

Constraints:
(28.1) is_constructible_v<T, const U&> is true, and
(28.2) if T is not cv bool, converts-from-any-cvref<T, optional<U>> is false.

Effects: If rhs contains a value, direct-non-list-initializes the contained value with *rhs.
Postconditions: rhs.has_value() == this->has_value().
Throws: Any exception thrown by the selected constructor of T.
Remarks: The expression inside explicit is equivalent to:
!is_convertible_v<const U&, T>

template<class U> constexpr explicit(see below) optional(optional<U>&& rhs);

Constraints:
(33.1) is_constructible_v<T, U> is true, and
(33.2) if T is not cv bool, converts-from-any-cvref<T, optional<U>> is false.

Effects: If rhs contains a value, direct-non-list-initializes the contained value with std::move(*rhs).
rhs.has_value() is unchanged.
Postconditions: rhs.has_value() == this->has_value().
Throws: Any exception thrown by the selected constructor of T.
Remarks: The expression inside explicit is equivalent to:
!is_convertible_v<U, T>

22.5.3.3 Destructor

constexpr ~optional();

Effects: If is_trivially_destructible_v<T> != true and *this contains a value, calls
val->T::~T()

Remarks: If is_trivially_destructible_v<T> is true, then this destructor is trivial.

22.5.3.4 Assignment

constexpr optional<T>& operator=(nullopt_t) noexcept;

Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.

Postconditions: *this does not contain a value.
Returns: *this.

constexpr optional<T>& operator=(const optional& rhs);

Effects: See Table 58.

Table 58 — optional::operator=(const optional&) effects

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>assigns *rhs to the contained value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs does not contain a value</td>
<td>*this does not contain a value</td>
<td>direct-non-list-initializes the contained value with *rhs</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Postconditions: rhs.has_value() == this->has_value().
Returns: *this.
**Remarks:** If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to T’s copy constructor, no effect. If an exception is thrown during the call to T’s copy assignment, the state of its contained value is as defined by the exception safety guarantee of T’s copy assignment. This operator is defined as deleted unless `is_copy_constructible_v<T>` is true and `is_copyAssignable_v<T>` is true. If `is_trivially_copy_constructible_v<T> && is_trivially_copyAssignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

```cpp
constexpr optional& operator=(optional&& rhs) noexcept(see below);
```

**Constraints:** `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true.

**Effects:** See Table 59. The result of the expression `rhs.has_value()` remains unchanged.

**Table 59 — optional::operator=(optional&&) effects [tab:optional.assign.move]**

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns <code>std::move(*rhs)</code> to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
</tr>
</tbody>
</table>

**Postconditions:** `rhs.has_value() == this->has_value()`.

**Returns:** `*this`.

**Remarks:** The exception specification is equivalent to:

`is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>`

If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to T’s move constructor, the state of `*rhs.val` is determined by the exception safety guarantee of T’s move constructor. If an exception is thrown during the call to T’s move assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of T’s move assignment. If `is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

```cpp
template<class U = T> constexpr optional<T>& operator=(U&& v);
```

**Constraints:** `is_same_v<remove_cvref_t<U>, optional<T>>` is false, `conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>>` is false, `is_constructible_v<T, U>` is true, and `is_assignable_v<T&, const U&>` is true.

**Effects:** If `*this` contains a value, assigns `std::forward<U>(v)` to the contained value; otherwise direct-non-list-initializes the contained value with `std::move(*rhs)`.

**Postconditions:** `*this` contains a value.

**Returns:** `*this`.

**Remarks:** If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to T’s constructor, the state of v is determined by the exception safety guarantee of T’s constructor. If an exception is thrown during the call to T’s assignment, the state of `*val` and v is determined by the exception safety guarantee of T’s assignment.

```cpp
template<class U> constexpr optional<T>& operator=(const optional<U>& rhs);
```

**Constraints:**

(19.1) `is_constructible_v<T, const U&>` is true,

(19.2) `is_assignable_v<T&, const U&>` is true,

(19.3) `converts-from-any- cvref<T, optional<U>>` is false,

(19.4) `is_assignable_v<T&, optional<U>&>` is false,
— is_assignable_v<T&, optional<U>&> is false,
— is_assignable_v<T&, const optional<U>&> is false, and
— is_assignable_v<T&, const optional<U>&&> is false.

Effects: See Table 60.

### Table 60 — optional::operator=(const optional<U>&) effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns *rhs to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
</tr>
</tbody>
</table>

Postconditions: rhs.has_value() == this->has_value().
Returns: *this.
Remarks: If any exception is thrown, the result of the expression this->has_value() remains unchanged. If an exception is thrown during the call to T's constructor, the state of *rhs.val is determined by the exception safety guarantee of T's constructor. If an exception is thrown during the call to T's assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T's assignment.

#### Constraints:

- is_constructible_v<T, U> is true,
- is_assignable_v<T&, U> is true,
- converts-from-any-cvref<T, optional<U>>& is true,
- is_assignable_v<T&, optional<U>&> is false,
- is_assignable_v<T&, optional<U>&&> is false, and
- is_assignable_v<T&, const optional<U>&> is false, and
- is_assignable_v<T&, const optional<U>&&> is false.

Effects: See Table 61. The result of the expression rhs.has_value() remains unchanged.

### Table 61 — optional::operator=(optional<U>&&) effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns std::move(*rhs) to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
</tr>
</tbody>
</table>

Postconditions: rhs.has_value() == this->has_value().
Returns: *this.
Remarks: If any exception is thrown, the result of the expression this->has_value() remains unchanged. If an exception is thrown during the call to T's constructor, the state of *rhs.val is determined by the exception safety guarantee of T's constructor. If an exception is thrown during the call to T's assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T's assignment.
template<class... Args> constexpr T& emplace(Args&&... args);

Mandates: is_constructible_v<T, Args...> is true.

Effects: Calls *this = nullopt. Then direct-non-list-initializes the contained value with std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed.

template<class U, class... Args> constexpr T& emplace(initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Calls *this = nullopt. Then direct-non-list-initializes the contained value with il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed.

22.5.3.5 Swap [optional.swap]

constexpr void swap(optional& rhs) noexcept(see below);

Mandates: is_move_constructible_v<T> is true.

Preconditions: T meets the Cpp17Swappable requirements (16.4.4.3).

Effects: See Table 62.

Table 62 — optional::swap(optional&) effects [tab:optional.swap]

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rhs contains a value</strong></td>
<td>calls swap(*(*this), *rhs)</td>
</tr>
<tr>
<td><strong>rhs does not contain a value</strong></td>
<td>direct-non-list-initializes the contained value of rhs with std::move(*(*this)), followed by val-&gt;T::~T(); postcondition is that *this does not contain a value and rhs contains a value</td>
</tr>
</tbody>
</table>

Throws: Any exceptions thrown by the operations in the relevant part of Table 62.

Remarks: The exception specification is equivalent to:

is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T>

If any exception is thrown, the results of the expressions this->has_value() and rhs.has_value() remain unchanged. If an exception is thrown during the call to function swap, the state of *val and *rhs.val is determined by the exception safety guarantee of swap for lvalues of T. If an exception is
thrown during the call to T's move constructor, the state of *val and *rhs.val is determined by the exception safety guarantee of T's move constructor.

22.5.3.6 Observers

```cpp
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;

1 Preconditions: *this contains a value.
2 Returns: val.
3 Remarks: These functions are constexpr functions.

constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;

4 Preconditions: *this contains a value.
5 Returns: *val.
6 Remarks: These functions are constexpr functions.

constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;

7 Preconditions: *this contains a value.
8 Effects: Equivalent to: return std::move(*val);

constexpr explicit operator bool() const noexcept;

9 Returns: true if and only if *this contains a value.
10 Remarks: This function is a constexpr function.

constexpr bool has_value() const noexcept;
11 Returns: true if and only if *this contains a value.
12 Remarks: This function is a constexpr function.

constexpr const T& value() const &;
constexpr T& value() &;
13 Effects: Equivalent to:
14 return has_value() ? *val : throw bad_optional_access();

constexpr T&& value() &&;
constexpr const T&& value() const &&;
15 Effects: Equivalent to:
16 return has_value() ? std::move(*val) : throw bad_optional_access();

template<class U> constexpr T value_or(U&& v) const &;
17 Mandates: is_copy_constructible_v<T> && is_convertible_v<U&&, T> is true.
18 Effects: Equivalent to:
19 return has_value() ? **this : static_cast<T>(std::forward<U>(v));

template<class U> constexpr T value_or(U&& v) &&;
20 Mandates: is_move_constructible_v<T> && is_convertible_v<U&&, T> is true.
21 Effects: Equivalent to:
22 return has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v));
```

22.5.3.7 Monadic operations

```cpp
template<class F> constexpr auto and_then(F&& f) &;
```

```cpp
template<class F> constexpr auto_and_then(const F& f) &;
```

22.5.3.7 Monadic operations

```cpp
Let U be invoke_result_t<T, decltype(*val)>.```
Mandates: `remove_cvref_t<\text{U}>` is a specialization of `optional`.

Effects: Equivalent to:

```cpp
define if (\*this) {
    return invoke(std::forward<F>(f), *val);
} else {
    return remove_cvref_t<\text{U}>();
}
```

```cpp
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let `\text{U}` be `invoke_result_t<F, decltype(std::move(*val))>`.

Mandates: `remove_cvref_t<\text{U}>` is a specialization of `optional`.

Effects: Equivalent to:

```cpp
define if (\*this) {
    return invoke(std::forward<F>(f), std::move(*val));
} else {
    return remove_cvref_t<\text{U}>();
}
```

```cpp
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

Let `\text{U}` be `remove_cv_t<invoke_result_t<F, decltype(std::move(*val))>>.`

Mandates: `\text{U}` is a non-array object type other than `in_place_t` or `nullopt_t`. The declaration

```cpp
\text{U} u(invoke(std::forward<F>(f), *val));
```

is well-formed for some invented variable `u`.

[Note 1: There is no requirement that \text{U} is movable (9.4.1). — end note]

Returns: If `\*this` contains a value, an `optional<\text{U}>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), *val)`; otherwise, `optional<\text{U}>()`.

```cpp
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

Let `\text{U}` be `remove_cv_t<invoke_result_t<F, decltype(std::move(*val))>>.`

Mandates: `\text{U}` is a non-array object type other than `in_place_t` or `nullopt_t`. The declaration

```cpp
\text{U} u(invoke(std::forward<F>(f), std::move(*val)));
```

is well-formed for some invented variable `u`.

[Note 2: There is no requirement that \text{U} is movable (9.4.1). — end note]

Returns: If `\*this` contains a value, an `optional<\text{U}>` object whose contained value is direct-non-list-initialized with `invoke(std::forward<F>(f), std::move(*val))`; otherwise, `optional<\text{U}>()`.

```cpp
template<class F> constexpr optional or_else(F&& f) const &;
```

Constraints: `F` models `invocable<>` and `T` models `copy_constructible`.

Mandates: `is_same_v<remove_cvref_t<\text{U}>\text{t}<\text{F}>, optional>` is true.

Effects: Equivalent to:

```cpp
define if (*this) {
    return *this;
} else {
    return std::forward<F>(f)();
}
```

```cpp
template<class F> constexpr optional or_else(F&& f) &&;
```

Constraints: `F` models `invocable<>` and `T` models `move_constructible`.

Mandates: `is_same_v<remove_cvref_t<\text{U}>\text{t}<\text{F}>, optional>` is true.

Effects: Equivalent to:

[§ 22.5.3.7 727]
if (*this) {
    return std::move(*this);
} else {
    return std::forward<F>(f)();
}

22.5.3.8 Modifiers  [optional.mod]

constexpr void reset() noexcept;

1  Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.

2  Postconditions: *this does not contain a value.

22.5.4 No-value state indicator  [optional.nullopt]

struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);

1  The struct nullopt_t is an empty class type used as a unique type to indicate the state of not containing a value for optional objects. In particular, optional<T> has a constructor with nullopt_t as a single argument; this indicates that an optional object not containing a value shall be constructed.

2  Type nullopt_t shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

22.5.5 Class bad_optional_access  [optional.bad.access]

namespace std {
    class bad_optional_access : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

1  The class bad_optional_access defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

const char* what() const noexcept override;

2  Returns: An implementation-defined NTBS.

22.5.6 Relational operators  [optional.relops]

template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);

1  Mandates: The expression *x == *y is well-formed and its result is convertible to bool.

[Note 1: T need not be Cpp17EqualityComparable. — end note]

2  Returns: If x.has_value() != y.has_value(), false; otherwise if x.has_value() == false, true; otherwise *x == *y.

3  Remarks: Specializations of this function template for which *x == *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);

4  Mandates: The expression *x != *y is well-formed and its result is convertible to bool.

5  Returns: If x.has_value() != y.has_value(), true; otherwise if x.has_value() == false, false; otherwise *x != *y.

6  Remarks: Specializations of this function template for which *x != *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);

7  Mandates: *x < *y is well-formed and its result is convertible to bool.

8  Returns: If !y, false; otherwise, if !x, true; otherwise *x < *y.
Remarks: Specializations of this function template for which \( *x < *y \) is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression \( *x > *y \) is well-formed and its result is convertible to bool.

Returns: If \(!x\), false; otherwise, if \(!y\), true; otherwise \( *x > *y \).

Remarks: Specializations of this function template for which \( *x > *y \) is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression \( *x \leq *y \) is well-formed and its result is convertible to bool.

Returns: If \(!x\), true; otherwise, if \(!y\), false; otherwise \( *x \leq *y \).

Remarks: Specializations of this function template for which \( *x \leq *y \) is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);
```

Mandates: The expression \( *x \geq *y \) is well-formed and its result is convertible to bool.

Returns: If \(!y\), true; otherwise, if \(!x\), false; otherwise \( *x \geq *y \).

Remarks: Specializations of this function template for which \( *x \geq *y \) is a core constant expression are constexpr functions.

```cpp
template<class T, three_way_comparable_with<T> U> constexpr compare_three_way_result_t<T, U> operator<=>(const optional<T>& x, const optional<U>& y);
```

Returns: If \( x \&\& y \), \( *x \triangleleft \bullet y \); otherwise \( x\text{.has\_value()} \triangleleft \bullet y\text{.has\_value()} \).

Remarks: Specializations of this function template for which \( *x \triangleleft \bullet y \) is a core constant expression are constexpr functions.

#### 22.5.7 Comparison with nullopt

```cpp
template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```

Returns: !x.

```cpp
template<class T> constexpr strong_ordering operator<=>(const optional<T>& x, nullopt_t) noexcept;
```

Returns: \( x\text{.has\_value()} \triangleleft \bullet \text{false} \).

#### 22.5.8 Comparison with T

```cpp
template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
```

Mandates: The expression \( *x == v \) is well-formed and its result is convertible to bool.

[Note 1: \( T \) need not be \( \text{Cpp17EqualityComparable} \). — end note]

Effects: Equivalent to: \( \text{return } x\text{.has\_value()} \ ? \ *x == v : \text{false}; \)

```cpp
template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
```

Mandates: The expression \( v == *x \) is well-formed and its result is convertible to bool.

Effects: Equivalent to: \( \text{return } x\text{.has\_value()} \ ? \ v == *x : \text{false}; \)

```cpp
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
```

Mandates: The expression \( *x \neq v \) is well-formed and its result is convertible to bool.

Effects: Equivalent to: \( \text{return } x\text{.has\_value()} \ ? \ *x \neq v : \text{true}; \)

```cpp
template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
```

Mandates: The expression \( v \neq *x \) is well-formed and its result is convertible to bool.

Effects: Equivalent to: \( \text{return } x\text{.has\_value()} \ ? \ v \neq *x : \text{true}; \)
template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);

Mandates: The expression \(*x < v\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? *x < v : true;

template<class T, class U> constexpr bool operator<(const T& v, const optional<U>& x);

Mandates: The expression \(v < *x\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? v < *x : false;

template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);

Mandates: The expression \(*x > v\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? *x > v : false;

template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);

Mandates: The expression \(v > *x\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? v > *x : true;

template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);

Mandates: The expression \(*x <= v\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? *x <= v : true;

template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);

Mandates: The expression \(v <= *x\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? v <= *x : false;

template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);

Mandates: The expression \(*x >= v\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? *x >= v : false;

template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);

Mandates: The expression \(v >= *x\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? v >= *x : true;

template<class T, class U> requires (!is_derived_from_optional<U>()) && three_way_comparable_with<T, U>
constexpr compare_three_way_result_t<T, U> operator<=>(const optional<T>& x, const U& v);

Mandates: The expression \(*x <=> v\) is well-formed and its result is convertible to bool.
Effects: Equivalent to: return x.has_value() ? *x <=> v : strong_ordering::less;

22.5.9 Specialized algorithms

22.5.9.730
22.5.10 Hash support

The specialization hash<optional<T>> is enabled (22.10.19) if and only if hash<remove_const_t<T>> is enabled. When enabled, for an object o of type optional<T>, if o.has_value() == true, then hash<optional<T>>()(o) evaluates to the same value as hash<remove_const_t<T>>()(*o); otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

22.6 Variants

22.6.1 In general

1 A variant object holds and manages the lifetime of a value. If the variant holds a value, that value’s type has to be one of the template argument types given to variant. These template arguments are called alternatives.

2 In subclause 22.6, GET denotes a set of exposition-only function templates (22.6.5).

22.6.2 Header <variant> synopsis

```cpp
#include <compare>  // see 17.11.1
namespace std {
    namespace {
        // 22.6.3, class template
        template<class... Types>
            class variant;
        // 22.6.4, variant helper classes
        template<class T>
            struct variant_size;  // not defined
        template<class T>
            struct variant_size<const T>;
        template<class T>
            constexpr size_t variant_size_v = variant_size<T>::value;
        template<class... Types>
            struct variant_size<variant<Types...>>;
        template<size_t I, class... Types>
            struct variant_alternative;
        template<size_t I, class... Types>
            using variant_alternative_t = typename variant_alternative<I, variant<Types...>>::type;
        template<size_t I, class... Types>
            constexpr size_t variant_npos = -1;
        // 22.6.5, value access
        template<class T, class... Types>
            constexpr bool holds_alternative(const variant<Types...>&) noexcept;
        template<size_t I, class... Types>
            constexpr variant_alternative_t<I, variant<Types...>>&
                get(variant<Types...>&);
        template<size_t I, class... Types>
            constexpr const variant_alternative_t<I, variant<Types...>>&
                get(const variant<Types...>&);  // freestanding-deleted
        template<size_t I, class... Types>
            constexpr variant_alternative_t<I, variant<Types...>>&
                get(variant<Types...>&&);
        template<size_t I, class... Types>

        constexpr decltype(auto) visit(this Self&, Visitor&);
        template<class R, class Self, class Visitor>
        constexpr R visit(this Self&, Visitor&);
    };
}

1 Any instance of variant at any given time either holds a value of one of its alternative types or holds no value. When an instance of variant holds a value of alternative type T, it means that a value of type T,
referred to as the `variant` object’s contained value, is allocated within the storage of the `variant` object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value.

2 All types in `Types` shall meet the `Cpp17Destructible` requirements (Table 35).

3 A program that instantiates the definition of `variant` with no template arguments is ill-formed.

4 If a program declares an explicit or partial specialization of `variant`, the program is ill-formed, no diagnostic required.

22.6.3.2 Constructors

In the descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}\ldots(\text{Types})]\), and \( T_i \) be the \( i \)th type in `Types`.

```cpp
constexpr variant() noexcept(see below);

Constraints: `is_default_constructible_v<T_0>` is true.

Effects: Constructs a `variant` holding a value-initialized value of type \( T_0 \).

Postconditions: `valueless_by_exception()` is false and `index()` is 0.

Throws: Any exception thrown by the value-initialization of \( T_0 \).

Remarks: This function is constexpr if and only if the value-initialization of the alternative type \( T_0 \) would be constexpr-suitable (9.2.6). The exception specification is equivalent to `is_nothrow_default_constructible_v<T_0>`.

[Note 1: See also class `monostate`. — end note]
```

```cpp
constexpr variant(const variant& w);

Effects: If \( w \) holds a value, initializes the `variant` to hold the same alternative as \( w \) and direct-initializes the contained value with `GET<j>(w)`, where \( j \) is \( w.index() \). Otherwise, initializes the `variant` to not hold a value.

Throws: Any exception thrown by direct-initializing any \( T_i \) for all \( i \).

Remarks: This constructor is defined as deleted unless `is_copy_constructible_v<T_i>` is true for all \( i \). If `is_trivially_copy_constructible_v<T_i>` is true for all \( i \), this constructor is trivial.
```

```cpp
constexpr variant(variant&& w) noexcept(see below);

Constraints: `is_move_constructible_v<T_i>` is true for all \( i \).

Effects: If \( w \) holds a value, initializes the `variant` to hold the same alternative as \( w \) and direct-initializes the contained value with `GET<j>(\text{std::move}(w))`, where \( j \) is \( w.index() \). Otherwise, initializes the `variant` to not hold a value.

Throws: Any exception thrown by move-constructing any \( T_i \) for all \( i \).

Remarks: The exception specification is equivalent to the logical AND of `is_nothrow_move_constructible_v<T_i>` for all \( i \). If `is_trivially_move_constructible_v<T_i>` is true for all \( i \), this constructor is trivial.
```

```cpp
template<class T> constexpr variant(T&& t) noexcept(see below);

Let \( T_j \) be a type that is determined as follows: build an imaginary function `FUN(T_i)` for each alternative type \( T_i \) for which \( T_i \times[] = \{\text{std::forward}<T>(t)\} \) is well-formed for some invented variable \( x \). The overload `FUN(T_j)` selected by overload resolution for the expression `FUN(\text{std::forward}<T>(t))` defines the alternative \( T_j \) which is the type of the contained value after construction.

Constraints:

- `sizeof...(Types)` is nonzero,
- `is_same_v<remove_cvref_t<T>, variant>` is false,
- `remove_cvref_t<T>` is neither a specialization of `in_place_type_t` nor a specialization of `in_place_index_t`,
- `is_constructible_v<T_j, T>` is true, and
- the expression `FUN(\text{std::forward}<T>(t))` (with `FUN` being the above-mentioned set of imaginary functions) is well-formed.
```
[Note 2:

\[\texttt{variant<string, string> v("abc")};\]

is formed, as both alternative types have an equally viable constructor for the argument. — end note]

Effects: Initializes *this to hold the alternative type \(T_j\) and direct-non-list-initializes the contained value with `std::forward<T_j>(t)`.

Postconditions: `holds_alternative<T_j>(*this)` is true.

Throws: Any exception thrown by the initialization of the selected alternative \(T_j\).

Remarks: The exception specification is equivalent to `is_nothrow_constructible_v<T_j, T>`.

If \(T_j\)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

\[
\text{template<class }T, \text{ class... Args}> \text{ constexpr explicit variant(in_place_type_t<T>, Args&&... args);} \]

Constraints:

1. There is exactly one occurrence of \(T\) in `Types`... and
2. `is_constructible_v<T, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type \(T\) with `std::forward<Args>(args)`...

Postconditions: `holds_alternative<T>(*this)` is true.

Throws: Any exception thrown by calling the selected constructor of \(T\).

Remarks: If \(T\)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

\[
\text{template<class }T, \text{ class U, class... Args}> \text{ constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);} \]

Constraints:

1. There is exactly one occurrence of \(T\) in `Types`... and
2. `is_constructible_v<T, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type \(T\) with `il, std::forward<Args>(args)`...

Postconditions: `holds_alternative<T>(*this)` is true.

Throws: Any exception thrown by calling the selected constructor of \(T\).

Remarks: If \(T\)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

\[
\text{template<size_t }I, \text{ class... Args}> \text{ constexpr explicit variant(in_place_index_t<I>, Args&&... args);} \]

Constraints:

1. \(I\) is less than `sizeof...(Types)` and
2. `is_constructible_v<T_I, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type \(T_I\) with `std::forward<Args>(args)`...

Postconditions: `index()` is \(I\).

Throws: Any exception thrown by calling the selected constructor of \(T_I\).

Remarks: If \(T_I\)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

\[
\text{template<size_t }I, \text{ class U, class... Args}> \text{ constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);} \]

Constraints:

1. \(I\) is less than `sizeof...(Types)` and
2. `is_constructible_v<T_I, initializer_list<U>&, Args...>` is true.

Effects: Direct-non-list-initializes the contained value of type \(T_I\) with `il, std::forward<Args>(args)`...
Postconditions: index() is I.

Remarks: If T_I's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

22.6.3.3 Destructor [variant.dtor]

constexpr ~variant();

1 Effects: If valueless_by_exception() is false, destroys the currently contained value.

2 Remarks: If is_trivially_destructible_v<T_I> is true for all T_i, then this destructor is trivial.

22.6.3.4 Assignment [variant.assign]

constexpr variant& operator=(const variant& rhs);

1 Let j be rhs.index().

2 Effects:

(2.1) — If neither *this nor rhs holds a value, there is no effect.

(2.2) — Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.

(2.3) — Otherwise, if index() == j, assigns the value contained in rhs to the value contained in *this.

(2.4) — Otherwise, if either is_nothrow_copy_constructible_v<T_I> is true or is_nothrow_move_constructible_v<T_I> is false, equivalent to emplace<j>(GET<j>(rhs)).

(2.5) — Otherwise, equivalent to operator=(variant(rhs)).

3 Postconditions: index() == rhs.index().

4 Returns: *this.

5 Remarks: This operator is defined as deleted unless is_copy_constructible_v<T_I> && is_copy_assignable_v<T_I> is true for all i. If is_trivially_copy_constructible_v<T_I> && is_trivially_copy_assignable_v<T_I> && is_trivially_destructible_v<T_I> is true for all i, this assignment operator is trivial.

constexpr variant& operator=(variant&& rhs) noexcept(see below);

6 Let j be rhs.index().

7 Constraints: is_move_constructible_v<T_I> && is_move_assignable_v<T_I> is true for all i.

8 Effects:

(8.1) — If neither *this nor rhs holds a value, there is no effect.

(8.2) — Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.

(8.3) — Otherwise, if index() == j, assigns GET<j>(std::move(rhs)) to the value contained in *this.

(8.4) — Otherwise, equivalent to emplace<j>(GET<j>(std::move(rhs))).

9 Returns: *this.

10 Remarks: If is_trivially_move_constructible_v<T_I> && is_trivially_move_assignable_v<T_I> && is_trivially_destructible_v<T_I> is true for all i, this assignment operator is trivial. The exception specification is equivalent to is_nothrow_move_constructible_v<T_I> && is_nothrow_move_assignable_v<T_I> for all i.

(10.1) — If an exception is thrown during the call to T_j's move construction (with j being rhs.index()), the variant will hold no value.

(10.2) — If an exception is thrown during the call to T_j's move assignment, the state of the contained value is as defined by the exception safety guarantee of T_j's move assignment; index() will be j.

template<class T> constexpr variant& operator=(T&& t) noexcept(see below);

11 Let T_j be a type that is determined as follows: build an imaginary function FUN(T_i) for each alternative type T_i for which T_i x[] = {std::forward<T>(t)} is well-formed for some invented variable x. The
overload $\text{FUN}(T_j)$ selected by overload resolution for the expression $\text{FUN}(\text{std::forward}<T>(t))$ defines the alternative $T_j$ which is the type of the contained value after assignment.

**Constraints:**

- $\text{is\_same\_v<}\text{remove\_cv\_ref\_t}<T>, \text{variant}>\text{is false},$
- $\text{is\_assignable\_v<T_j, T> amp; amp; is\_constructible\_v<T_j, T> is true, and}$
- the expression $\text{FUN}(\text{std::forward}<T>(t))$ (with $\text{FUN}$ being the above-mentioned set of imaginary functions) is well-formed.

**Note 1:**

```
variant<string, string> v;
v = "abc";
```

is ill-formed, as both alternative types have an equally viable constructor for the argument. —end note

**Effects:**

- If $\ast \text{this}$ holds a $T_j$, assigns $\text{std::forward}<T>(t)$ to the value contained in $\ast \text{this}$.
- Otherwise, if $\text{is\_nothrow\_constructible}\_v<T_j, T> || \text{!is\_nothrow\_move\_constructible}\_v<T_j, T>$ is true, equivalent to $\text{emplace}\langle\text{J}\rangle(\text{std::forward}<T>(t))$.
- Otherwise, equivalent to $\text{emplace}\langle\text{J}\rangle(T_j(\text{std::forward}<T>(t)))$.

**Postconditions:** $\text{holds\_alternative}\_v<T_j>(\ast \text{this})$ is true, with $T_j$ selected by the imaginary function overload resolution described above.

**Returns:** $\ast \text{this}$.

**Remarks:** The exception specification is equivalent to:

- $\text{is\_nothrow\_assignable\_v<T_j, T> amp; amp; is\_nothrow\_constructible\_v<T_j, T>}$
- If an exception is thrown during the assignment of $\text{std::forward}<T>(t)$ to the value contained in $\ast \text{this}$, the state of the contained value and $t$ are as defined by the exception safety guarantee of the assignment expression; $\text{valueless\_by\_exception()}$ will be false.
- If an exception is thrown during the initialization of the contained value, the $\text{variant}$ object is permitted to not hold a value.

### 22.6.3.5 Modifiers

[variant.mod]

```
template<class T, class... Args> constexpr T& emplace(Args&&... args);
```

**Constraints:** $\text{is\_constructible}\_v<T, Args...>\text{is true, and T occurs exactly once in Types.}$

**Effects:** Equivalent to:

```
return emplace</>(\text{std::forward}<\text{Args}>(\text{args})...);
```

where $I$ is the zero-based index of $T$ in $\text{Types}.$

```
template<class T, class U, class... Args>
constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

**Constraints:** $\text{is\_constructible}\_v<T, initializer\_list<U>\&, Args...>\text{is true, and T occurs exactly once in Types.}$

**Effects:** Equivalent to:

```
return emplace</>(il, \text{std::forward}<\text{Args}>(\text{args})...);
```

where $I$ is the zero-based index of $T$ in $\text{Types}.$

```
template<\text{size}\_t I, class... Args>
constexpr \text{variant\_alternative}\_v<T I, variant<Types...>>\& emplace(Args&&... args);
```

**Mandates:** $I < \text{sizeof...}(\text{Types}).$

**Constraints:** $\text{is\_constructible}\_v<T_I, Args...>\text{is true.}$

**Effects:** Destroys the currently contained value if $\text{valueless\_by\_exception()}$ is false. Then direct-
non-list-initializes the contained value of type $T_I$ with the arguments $\text{std::forward}<\text{Args}>(\text{args})...$.

**Postconditions:** $\text{index()}$ is $I$. 

§ 22.6.3.5 737

10. Throws: Any exception thrown during the initialization of the contained value.

11. Remarks: If an exception is thrown during the initialization of the contained value, the variant is permitted to not hold a value.

\[\text{template<'}\text{size_t } I, \text{ class } U, \text{ class... } \text{ Args}\]
\[\text{constexpr } \text{variant\_alternative}_t<\text{I}, \text{ variant\_Types... } \text{&}_k\]
\[\text{emplace}(<\text{initializer\_list}<\text{U}> \text{ il, Args&}_k\text{... args}>);\]

12. Mandates: \(I < \text{sizeof...}(<\text{Types})\).

13. Constraints: is_constructible<\text{v<T_I>, initializer\_list<U>}, Args...> is true.

14. Effects: Destroys the currently contained value if valueless\_by\_exception() is false. Then direction-list-initializes the contained value of type T_I with il, std::forward<Args>(args)....

15. Postconditions: index() is I.

17. Throws: Any exception thrown during the initialization of the contained value.

18. Remarks: If an exception is thrown during the initialization of the contained value, the variant is permitted to not hold a value.

### 22.6.3.6 Value status

\[\text{constexpr } \text{bool } \text{valueless\_by\_exception()} \text{ const noexcept};\]

1. Effects: Returns false if and only if the variant holds a value.

[Note 1: It is possible for a variant to hold no value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a \(\text{variant<float, int>}\) can become valueless\_by\_exception(), for instance by

- struct S { operator int() { throw 42; } };
- \text{variant<float, int>} v{12.f};
- v.emplace<1>(S());
- end note]

\[\text{constexpr } \text{size\_t } \text{index()} \text{ const noexcept};\]

3. Effects: If valueless\_by\_exception() is true, returns variant\_npos. Otherwise, returns the zero-based index of the alternative of the contained value.

### 22.6.3.7 Swap

\[\text{constexpr } \text{void } \text{swap}(<\text{variant}\& rhs) \text{ noexcept(see below)};\]

1. Mandates: is\_move\_constructible<\text{v<T_I>}, rhs> is true for all i.

2. Preconditions: Each T_i meets the Cpp17Swappable requirements (16.4.4.3).

3. Effects:

(3.1) If valueless\_by\_exception() \&\& rhs.valueless\_by\_exception() no effect.

(3.2) Otherwise, if index() == rhs.index(), calls swap(GET<i>(*this), GET<i>(rhs)) where i is index().

(3.3) Otherwise, exchanges values of rhs and *this.

4. Throws: If index() == rhs.index(), any exception thrown by swap(GET<i>(*this), GET<i>(rhs)) with i being index(). Otherwise, any exception thrown by the move constructor of T_i or T_j with i being index() and j being rhs.index().

5. Remarks: If an exception is thrown during the call to function swap(GET<i>(*this), GET<i>(rhs)), the states of the contained values of *this and of rhs are determined by the exception safety guarantee of swap for lvalues of T_i with i being index(). If an exception is thrown during the exchange of the values of *this and rhs, the states of the values of *this and of rhs are determined by the exception safety guarantee of variant’s move constructor. The exception specification is equivalent to the logical AND of is\_nothrow\_move\_constructible<\text{v<T_I>}, \&\& is\_nothrow\_swappable<\text{v<T_I>}} for all i.
22.6.4 variant helper classes

```
template<class T> struct variant_size;
```

1 All specializations of `variant_size` meet the `Cpp17UnaryTypeTrait` requirements (21.3.2) with a base characteristic of `integral_constant<size_t, N>` for some `N`.

```
template<class T> struct variant_size<const T>;
```

2 Let `VS` denote `variant_size<T>` of the cv-unqualified type `T`. Then each specialization of the template meets the `Cpp17UnaryTypeTrait` requirements (21.3.2) with a base characteristic of `integral_constant<size_t, VS::value>`.

```
template<class... Types>
struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> {
};
```

3 Let `VA` denote `variant_alternative<I, T>` of the cv-unqualified type `T`. Then each specialization of the template meets the `Cpp17TransformationTrait` requirements (21.3.2) with a member typedef `type` that names the type `add_const_t<VA::type>`.

```
 Mandates: I < sizeof...(Types).
Type: The type `T`.
```

22.6.5 Value access

```
template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

1 Mandates: The type `T` occurs exactly once in `Types`.

```
 Returns: true if `index()` is equal to the zero-based index of `T` in `Types`.
```

```
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>& GET(variant<Types...>& v);
```

3 Mandates: `I < sizeof...(Types)`.

```
 Returns: A reference to the object stored in the `variant`.
```

```
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>> get(variant<Types...>& v);
```

6 Mandates: `I < sizeof...(Types)`.

```
 Effects: If `v.index()` is `I`, returns a reference to the object stored in the `variant`. Otherwise, throws an exception of type `bad_variant_access`.
```
Mandates: The type \( T \) occurs exactly once in \( Types \).

Effects: If \( v \) holds a value of type \( T \), returns a reference to that value. Otherwise, throws an exception of type \( \text{bad\_variant\_access} \).

Mandates: \( I < \text{sizeof}(...) \).

Returns: A pointer to the value stored in the \( \text{variant} \), if \( v \neq \text{nullptr} \) and \( v->\text{index}() == I \). Otherwise, returns \( \text{nullptr} \).

Mandates: The type \( T \) occurs exactly once in \( Types \).

Effects: Equivalent to: \( \text{return get\_if}\langle i \rangle(v) \); with \( i \) being the zero-based index of \( T \) in \( Types \).

§ 22.6.6  Relational operators

Mandates: \( GET\langle i \rangle(v) == GET\langle i \rangle(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( v.\text{index}() \neq w.\text{index}() \), \( false \); otherwise if \( v.\text{valueless\_by\_exception}() \), \( true \); otherwise \( GET\langle i \rangle(v) == GET\langle i \rangle(w) \) with \( i \) being \( v.\text{index}() \).

Mandates: \( GET\langle i \rangle(v) \neq GET\langle i \rangle(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( v.\text{index}() \neq w.\text{index}() \), \( true \); otherwise if \( v.\text{valueless\_by\_exception}() \), \( false \); otherwise \( GET\langle i \rangle(v) \neq GET\langle i \rangle(w) \) with \( i \) being \( v.\text{index}() \).

Mandates: \( GET\langle i \rangle(v) < GET\langle i \rangle(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( w.\text{valueless\_by\_exception}() \), \( false \); otherwise if \( v.\text{valueless\_by\_exception}() \), \( true \); otherwise, if \( v.\text{index}() < w.\text{index}() \), \( true \); otherwise if \( v.\text{index}() > w.\text{index}() \), \( false \); otherwise \( GET\langle i \rangle(v) < GET\langle i \rangle(w) \) with \( i \) being \( v.\text{index}() \).

Mandates: \( GET\langle i \rangle(v) > GET\langle i \rangle(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( v.\text{valueless\_by\_exception}() \), \( false \); otherwise if \( w.\text{valueless\_by\_exception}() \), \( true \); otherwise, if \( v.\text{index}() > w.\text{index}() \), \( true \); otherwise if \( v.\text{index}() < w.\text{index}() \), \( false \); otherwise \( GET\langle i \rangle(v) > GET\langle i \rangle(w) \) with \( i \) being \( v.\text{index}() \).
template<class... Types>
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);

Mandates: \( \text{GET}<i>(v) \leq \text{GET}<i>(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( v.\text{valueless}_\text{by_exception}() \), true; otherwise if \( w.\text{valueless}_\text{by_exception}() \), false; otherwise if \( v.\text{index}() < w.\text{index}() \), true; otherwise if \( v.\text{index}() > w.\text{index}() \), false; otherwise \( \text{GET}<i>(v) \leq \text{GET}<i>(w) \) with \( i \) being \( v.\text{index}() \).

template<class... Types>
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);

Mandates: \( \text{GET}<i>(v) \geq \text{GET}<i>(w) \) is a valid expression that is convertible to bool, for all \( i \).

Returns: If \( w.\text{valueless}_\text{by_exception}() \), true; otherwise if \( v.\text{valueless}_\text{by_exception}() \), false; otherwise if \( v.\text{index}() > w.\text{index}() \), true; otherwise if \( v.\text{index}() < w.\text{index}() \), false; otherwise \( \text{GET}<i>(v) \geq \text{GET}<i>(w) \) with \( i \) being \( v.\text{index}() \).

template<class... Types> requires (three_way_comparable<Types> && ...) common_comparison_category_t<compare_three_way_result_t<Types>...>
operator<=>(const variant<Types...>& v, const variant<Types...>& w);

Effects: Equivalent to:
if (v.\text{valueless}_\text{by_exception}() && w.\text{valueless}_\text{by_exception}())
return strong\_ordering::\text{equal};
if (v.\text{valueless}_\text{by_exception}()) return strong\_ordering::\text{less};
if (w.\text{valueless}_\text{by_exception}()) return strong\_ordering::\text{greater};
if (auto c = v.\text{index}() <=> w.\text{index}(); c != 0) return c;
return \text{GET}<i>(v) <=> \text{GET}<i>(w);
with \( i \) being \( v.\text{index}() \).

22.6.7 Visitation

Let \( \text{as-variant} \) denote the following exposition-only function templates:

\begin{verbatim}
template<class... Ts>
auto&& \text{as-variant}(variant<Ts...>& var) { return var; }
template<class... Ts>
auto&& \text{as-variant}(const variant<Ts...>& var) { return var; }
template<class... Ts>
auto&& \text{as-variant}(variant<Ts...>&& var) { return std::move(var); }
template<class... Ts>
auto&& \text{as-variant}(const variant<Ts...>&& var) { return std::move(var); }
\end{verbatim}

Let \( n \) be \text{sizeof}(...\text{Variants}). For each \( 0 \leq i < n \), let \( V_i \) denote the type \( \text{decltype}(\text{as-variant}(\text{std::forward}<\text{Variants},>(\text{vars}_i))) \).

Constraints: \( V_i \) is a valid type for all \( 0 \leq i < n \).

Let \( V \) denote the pack of types \( V_i \).

Let \( m \) be a pack of \( n \) values of type \text{size\_t}. Such a pack is valid if
\( 0 \leq m_i < \text{variant\_size\_t}<\text{remove\_reference\_t}<V_i> \) for all \( 0 \leq i < n \). For each valid pack \( m \), let \( e(m) \) denote the expression:
\begin{verbatim}
INVOKED\langle\text{std::forward}<\text{Visitor}>(\text{vis}), \text{GET}<m>\langle\text{std::forward}<V>(\text{vars})\rangle\rangle // see 22.10.4
\end{verbatim}
for the first form and
\begin{verbatim}
INVOKED<R\rangle\langle\text{std::forward}<\text{Visitor}>(\text{vis}), \text{GET}<m>\langle\text{std::forward}<V>(\text{vars})\rangle\rangle // see 22.10.4
\end{verbatim}
for the second form.

Mandates: For each valid pack \( m \), \( e(m) \) is a valid expression. All such expressions are of the same type and value category.
Returns: $e(m)$, where $m$ is the pack for which $m_i$ is \texttt{as-variant(vara_i).index()} for all $0 \leq i < n$. The return type is \texttt{decltype(e(m))} for the first form.

Throws: \texttt{bad_variant_access} if \texttt{(as-variant(vara).valueless_by_exception() || ...)} is true.

Complexity: For $n \leq 1$, the invocation of the callable object is implemented in constant time, i.e., for $n = 1$, it does not depend on the number of alternative types of $V_0$. For $n > 1$, the invocation of the callable object has no complexity requirements.

```
template<class Self, class Visitor>
constexpr decltype(auto) visit(this Self&& self, Visitor&& vis);
```

Let $V$ be \texttt{OVERRIDE_REF(Self&&, COPY_CONST(\texttt{remove_reference_t<Self>, variant}) (22.2.4)).}

Constraints: The call to visit does not use an explicit template-argument-list that begins with a type template-argument.

Effects: Equivalent to: return \texttt{std::visit(std::forward<Visitor>(vis), (V)self)};

```
template<class R, class Self, class Visitor>
constexpr R visit(this Self&& self, Visitor&& vis);
```

Let $V$ be \texttt{OVERRIDE_REF(Self&&, COPY_CONST(\texttt{remove_reference_t<Self>, variant}) (22.2.4)).}

Effects: Equivalent to: return \texttt{std::visit<R>(std::forward<Visitor>(vis), (V)self)};

22.6.8 Class \texttt{monostate} [variant.monostate]

```
struct monostate{};
```

The class \texttt{monostate} can serve as a first alternative type for a \texttt{variant} to make the \texttt{variant} type default constructible.

22.6.9 \texttt{monostate} relational operators [variant.monostate.relops]

```
constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr strong_ordering operator<=>(monostate, monostate) noexcept { return strong_ordering::equal; }
```

[Note 1: \texttt{monostate} objects have only a single state; they thus always compare equal. — end note]

22.6.10 Specialized algorithms [variant.specalg]

```
template<class... Types>
constexpr void swap(variant<Types...>& v, variant<Types...>& w) noexcept(\texttt{see below});
```

Constraints: \texttt{is_move_constructible_v<T_i> \&\& is_swappable_v<T_i>} is true for all $i$.

Effects: Equivalent to \texttt{v.swap(w)}.

Remarks: The exception specification is equivalent to \texttt{noexcept(v.swap(w))}.

22.6.11 Class \texttt{bad_variant_access} [variant.bad.access]

```
namespace std {
  class bad_variant_access : public exception {
    public:
      // see 17.9.3 for the specification of the special member functions
      const char* what() const noexcept override;
  };
}
```

Objects of type \texttt{bad_variant_access} are thrown to report invalid accesses to the value of a \texttt{variant} object.

```
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

22.6.12 Hash support [variant.hash]

§ 22.6.12 742
template<class... Types> struct hash<variant<Types...>>;

The specialization hash<variant<Types...>> is enabled (22.10.19) if and only if every specialization in hash<remove_const_t<Types>>... is enabled. The member functions are not guaranteed to be

noexcept.

template<> struct hash<monostate>;

The specialization is enabled (22.10.19).

22.7 Storage for any type

22.7.1 General

Subclause 22.7 describes components that C++ programs may use to perform operations on objects of a discriminated type.

[Note 1: The discriminated type can contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an int and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. — end note]

22.7.2 Header <any> synopsis

namespace std {

    // 22.7.3, class bad_any_cast
    class bad_any_cast;

    // 22.7.4, class any
    class any;

    // 22.7.5, non-member functions
    void swap(any& x, any& y) noexcept;

template<class T, class... Args>
    any make_any(Args&&... args);

template<class T, class U, class... Args>
    any make_any(initializer_list<U> il, Args&&... args);

    template<class T>
    T any_cast(const any& operand);

template<class T>
    T any_cast(any& operand);

template<class T>
    T any_cast(any&& operand);

    template<class T>
    const T* any_cast(const any* operand) noexcept;

template<class T>
    T* any_cast(any* operand) noexcept;
}

22.7.3 Class bad_any_cast

namespace std {

class bad_any_cast : public bad_cast {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    }
}

1 Objects of type bad_any_cast are thrown by a failed any_cast (22.7.5).

    const char* what() const noexcept override;

2 Returns: An implementation-defined NTBS.
22.7.4 Class any

22.7.4.1 General

namespace std {
    class any {
        public:
            // 22.7.4.2, construction and destruction
            constexpr any() noexcept;
            any(const any& other);
            any(any&& other) noexcept;
            template<class T>
                any(T&& value);
            template<class T, class... Args>
                explicit any(in_place_type_t<T>, Args&&...);
            template<class T, class U, class... Args>
                explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
            ~any();
            // 22.7.4.3, assignments
            any& operator=(const any& rhs);
            any& operator=(any&& rhs) noexcept;
            template<class T>
                any& operator=(T&& rhs);
            // 22.7.4.4, modifiers
            template<class T, class... Args>
                decay_t<T>& emplace(Args&&...);
            template<class T, class U, class... Args>
                decay_t<T>& emplace(initializer_list<U>, Args&&...);
            void reset() noexcept;
            void swap(any& rhs) noexcept;
            // 22.7.4.5, observers
            bool has_value() const noexcept;
            const type_info& type() const noexcept;
    };
}

1 An object of class any stores an instance of any type that meets the constructor requirements or it has no
value, and this is referred to as the state of the class any object. The stored instance is called the contained
value. Two states are equivalent if either they both have no value, or they both have a value and the contained
values are equivalent.

2 The non-member any_cast functions provide type-safe access to the contained value.

3 Implementations should avoid the use of dynamically allocated memory for a small contained value. How-
ever, any such small-object optimization shall only be applied to types T for which is_nothrow_move-
constructible_v<T> is true.

[Example 1: A contained value of type int could be stored in an internal buffer, not in separately-allocated memory.
—end example]

22.7.4.2 Construction and destruction

constexpr any() noexcept;

1 Postconditions: has_value() is false.

any(const any& other);

2 Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, equivalent
to any(in_place_type<T>, any_cast<const T&>(other)) where T is the type of the contained value.
3  Throws: Any exceptions arising from calling the selected constructor for the contained value.

    any(any&& other) noexcept;

4  Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, constructs an object of type any that contains either the contained value of other, or contains an object of the same type constructed from the contained value of other considering that contained value as an rvalue.

template<class T>
any(T&& value);

5  Let VT be decay_t<T>.

6  Constraints: VT is not the same type as any, VT is not a specialization of in_place_type_t, and is_copy_constructible_v<VT> is true.

7  Preconditions: VT meets the Cpp17CopyConstructible requirements.

8  Effects: Constructs an object of type any that contains an object of type VT direct-initialized with std::forward<T>(value).

9  Throws: Any exception thrown by the selected constructor of VT.

template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);

10  Let VT be decay_t<T>.

11  Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

12  Preconditions: VT meets the Cpp17CopyConstructible requirements.

13  Effects: Direct-non-list-initializes the contained value of type VT with std::forward<Args>(args)....

14  Postconditions: *this contains a value of type VT.

15  Throws: Any exception thrown by the selected constructor of VT.

template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

16  Let VT be decay_t<T>.

17  Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U> &, Args...> is true.

18  Preconditions: VT meets the Cpp17CopyConstructible requirements.

19  Effects: Direct-non-list-initializes the contained value of type VT with il, std::forward<Args>(args)....

20  Postconditions: *this contains a value.

21  Throws: Any exception thrown by the selected constructor of VT.

22  ~any();

22.7.4.3 Assignment [any.assign]

any& operator=(const any& rhs);

1  Effects: As if by any(rhs).swap(*this). No effects if an exception is thrown.

2  Returns: *this.

3  Throws: Any exceptions arising from the copy constructor for the contained value.

any& operator=(any&& rhs) noexcept;

4  Effects: As if by any(std::move(rhs)).swap(*this).

5  Postconditions: The state of *this is equivalent to the original state of rhs.

6  Returns: *this.
template<class T>
any& operator=(T&& rhs);

Let VT be decay_t<T>.

Constraints: VT is not the same type as any and is_copy_constructible_v<VT> is true.

Preconditions: VT meets the CopyConstructible requirements.

Effects: Constructs an object tmp of type any that contains an object of type VT direct-initialized with std::forward<T>(rhs), and tmp.swap(*this). No effects if an exception is thrown.

Returns: *this.

Throws: Any exception thrown by the selected constructor of VT.

22.7.4.4 Modifiers [any.modifiers]

template<class T, class... Args>
decay_t<T>& emplace(Args&&... args);

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

Preconditions: VT meets the CopyConstructible requirements.

Effects: Calls reset(). Then direct-non-list-initializes the contained value of type VT with std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed.

template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>, Args...> is true.

Preconditions: VT meets the CopyConstructible requirements.

Effects: Calls reset(). Then direct-non-list-initializes the contained value of type VT with il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed.

void reset() noexcept;

Effects: If has_value() is true, destroys the contained value.

Postconditions: has_value() is false.

void swap(any& rhs) noexcept;

Effects: Exchanges the states of *this and rhs.

22.7.4.5 Observers [any.observers]

bool has_value() const noexcept;

Returns: true if *this contains an object, otherwise false.
const type_info& type() const noexcept;

Returns: typeid(T) if this has a contained value of type T, otherwise typeid(void).

[Note 1: Useful for querying against types known either at compile time or only at runtime. — end note]

22.7.5  Non-member functions

void swap(any& x, any& y) noexcept;

Effects: Equivalent to x.swap(y).

template<class T, class... Args>
any make_any(Args&&... args);

Effects: Equivalent to: return any(in_place_type<T>, std::forward<Args>(args)...);

template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&&... args);

Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);

template<class T>
T any_cast(const any& operand);
template<class T>
T any_cast(any& operand);
template<class T>
T any_cast(any&& operand);

Let U be the type remove_cvref_t<T>.

Mandates: For the first overload, is_constructible_v<T, const U&> is true. For the second overload, is_constructible_v<T, U&> is true. For the third overload, is_constructible_v<T, U> is true.

Returns: For the first and second overload, static_cast<T>(*any_cast<U>(&operand)). For the third overload, static_cast<T>(std::move(*any_cast<U>(&operand))).

Throws: bad_any_cast if operand.type() != typeid(remove_reference_t<T>.

[Example 1:

any x(5);
assert(any_cast<int>(x) == 5); // cast to value
any_cast<int&>(x) = 10; // cast to reference
assert(any_cast<int>(x) == 10);

x = "Meow"; // x holds const char*
assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
any_cast<const char&>(x) = "Harry";
assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

x = string("Meow"); // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x)); // move from any
assert(s == "Meow");
any_cast<string&>(x) = move(s2); // move to any
assert(any_cast<const string&>(x) == "Meow");

string cat("Meow");
const any y(cat); // const y holds string
assert(any_cast<const string&>(y) == cat);

any_cast<string&>(y); // error: cannot any_cast away const
— end example]

template<class T>
const T* any_cast(const any* operand) noexcept;
template<class T>
T* any_cast(any* operand) noexcept;

Mandates: is_void_v<T> is false.
Returns: If operand != nullptr && operand->type() == typeid(T) is true, a pointer to the object contained by operand; otherwise, nullptr.

[Example 2:
bool is_string(const any& operand) {
    return any_cast<string>(operand) != nullptr;
}
— end example]

22.8 Expected objects

22.8.1 In general

Subclause 22.8 describes the class template `expected` that represents expected objects. An `expected<T, E>` object holds an object of type T or an object of type E and manages the lifetime of the contained objects.

22.8.2 Header `<expected>` synopsis

```cpp
// mostly freestanding
namespace std {
    // 22.8.3, class template unexpected
template<class E> class unexpected;

    // 22.8.4, class template bad_expected_access
template<class E> class bad_expected_access;

    // 22.8.5, specialization for void
template<> class bad_expected_access<void>;

    // in-place construction of unexpected values
struct unexpect_t {
    explicit unexpect_t() = default;
};
inline constexpr unexpect_t unexpect{};

    // 22.8.6, class template expected
template<class T, class E> class expected; // partially freestanding

    // 22.8.7, partial specialization of expected for void types
template<class T, class E> requires is_void_v<T> class expected<T, E>; // partially freestanding
}
```

22.8.3 Class template unexpected

22.8.3.1 General

Subclause 22.8.3 describes the class template `unexpected` that represents unexpected objects stored in `expected` objects.

```cpp
namespace std {
    template<class E>
    class unexpected {
        public:
            // 22.8.3.2, constructors
            constexpr unexpected(const unexpected&) = default;
            constexpr unexpected(unexpected&&) = default;
            template<class Err = E>
            constexpr explicit unexpected(Err&&);
            template<class... Args>
            constexpr explicit unexpected(in_place_t, Args&&...);
            template<class U, class... Args>
            constexpr explicit unexpected(in_place_t, initializer_list<U>, Args&&...);

            constexpr unexpected& operator=(const unexpected&) = default;
            constexpr unexpected& operator=(unexpected&&) = default;
        }
```
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
constexpr const E&& error() const && noexcept;
constexpr E&& error() && noexcept;
constexpr void swap(unexpected& other) noexcept;

template<class E2>
friend constexpr bool operator==(const unexpected&, const unexpected<E2>&);

friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));

private:
    E unex; // exposition only
};

template<class E> unexpected(E) -> unexpected<E>;

A program that instantiates the definition of unexpected for a non-object type, an array type, a specialization of unexpected, or a cv-qualified type is ill-formed.

22.8.3.2 Constructors

template<class Err = E>
constexpr explicit unexpected(Err&& e);

Constraints:
(1.1) is_same_v<remove_cvref_t<Err>, unexpected> is false; and
(1.2) is_same_v<remove_cvref_t<Err>, in_place_t> is false; and
(1.3) is_constructible_v<E, Err> is true.

Effects: Direct-non-list-initializes unex with std::forward<Err>(e).

Throws: Any exception thrown by the initialization of unex.

template<class... Args>
constexpr explicit unexpected(in_place_t, Args&&... args);

Constraints: is_constructible_v<E, Args...> is true.

Effects: Direct-non-list-initializes unex with std::forward<Args>(args)....

Throws: Any exception thrown by the initialization of unex.

template<class U, class... Args>
constexpr explicit unexpected(in_place_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<E, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes unex with il, std::forward<Args>(args)....

Throws: Any exception thrown by the initialization of unex.

22.8.3.3 Observers

constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;

Returns: unex.

constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;

Returns: std::move(unex).

22.8.3.4 Swap

constexpr void swap(unexpected& other) noexcept(is_nothrow_swappable_v<E>);

Mandates: is_swappable_v<E> is true.
Effects: Equivalent to: using std::swap; swap(unex, other.unex);
friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));

Constraints: is_swappable_v<E> is true.

Effects: Equivalent to x.swap(y).

22.8.3.5 Equality operator

template<class E2>
friend constexpr bool operator==(const unexpected& x, const unexpected<E2>& y);

Mandates: The expression x.error() == y.error() is well-formed and its result is convertible to bool.

Returns: x.error() == y.error().

22.8.4 Class template bad_expected_access

namespace std {

template<class E>
class bad_expected_access : public bad_expected_access<void> {
  public:
    explicit bad_expected_access(E);
    const char* what() const noexcept override;
    E& error() & noexcept;
    const E& error() const & noexcept;
    E&& error() && noexcept;
    const E&& error() const && noexcept;

  private:
    E unex; // exposition only
};
}

The class template bad_expected_access defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an expected<T, E> object for which has_value() is false.

explicit bad_expected_access(E e);

Effects: Initializes unex with std::move(e).

const E& error() const & noexcept;
E& error() & noexcept;

Returns: unex.

E&& error() && noexcept;
const E&& error() const & noexcept;

Returns: std::move(unex).

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

22.8.5 Class template specialization bad_expected_access<void>

namespace std {

template<class E>
class bad_expected_access : public exception {
  protected:
    bad_expected_access() noexcept;
    bad_expected_access(const bad_expected_access&);
    bad_expected_access(bad_expected_access&&);
    bad_expected_access& operator=(const bad_expected_access&);
    bad_expected_access& operator=(bad_expected_access&&);
    ~bad_expected_access();

  public:
    bad_expected_access( );
    bad_expected_access(const bad_expected_access&);
    bad_expected_access(bad_expected_access&&);
    bad_expected_access& operator=(const bad_expected_access&);
    bad_expected_access& operator=(bad_expected_access&&);
    ~bad_expected_access();

};

§ 22.8.5
public:
  const char* what() const noexcept override;
};

const char* what() const noexcept override;

Returns: An implementation-defined `ntbs`.

22.8.6 Class template expected

22.8.6.1 General

namespace std {
  template<class T, class E>
  class expected {
    public:
      using value_type = T;
      using error_type = E;
      using unexpected_type = unexpected<E>;

      template<class U>
      using rebind = expected<U, error_type>;

      // 22.8.6.2, constructors
      constexpr expected();
      constexpr expected(const expected&);
      constexpr expected(expected&&) noexcept);
      template<class U, class G>
      constexpr explicit(see below) expected(const expected<U, G>&);
      template<class U, class G>
      constexpr explicit(see below) expected(expected<U, G>&&);

      template<class U = T>
      constexpr explicit(see below) expected(U& v);

      template<class G>
      constexpr explicit(see below) expected(const unexpected<G>&);
      template<class G>
      constexpr explicit(see below) expected(unexpected<G>&&);

      template<class... Args>
      constexpr explicit expected(in_place_t, Args&&...);
      template<class U, class... Args>
      constexpr explicit expected(in_place_t, initializer_list<U>, Args&&...);
      template<class... Args>
      constexpr T& emplace(Args&&...) noexcept;
      template<class U, class... Args>
      constexpr T& emplace(initializer_list<U>, Args&&...) noexcept;

      // 22.8.6.3, destructor
      constexpr ~expected();

      // 22.8.6.4, assignment
      constexpr expected& operator=(const expected&);
      constexpr expected& operator=(expected&) noexcept(see below);
      template<class U = T> constexpr expected& operator=(U&);
      template<class G>
      constexpr expected& operator=(const unexpected<G>&);
      template<class G>
      constexpr expected& operator=(unexpected<G>&&);

      template<class... Args>
      constexpr T& emplace(Args&&...) noexcept;
      template<class U, class... Args>
      constexpr T& emplace(initializer_list<U>, Args&&...) noexcept;

§ 22.8.6.1
// 22.8.6.5, swap
constexpr void swap(expected&) noexcept(see below);
friend constexpr void swap(expected x, expected y) noexcept(noexcept(x.swap(y)));
the object of type T or the object of type E. Member has_val indicates whether the expected<T, E> object contains an object of type T.

2 A type T is a valid value type for expected if remove_cv_t<T> is void or a complete non-array object type that is not in_place_t, unexpected_t, or a specialization of unexpected_t. A program which instantiates class template expected<T, E> with an argument T that is not a valid value type for expected is ill-formed. A program that instantiates the definition of the template expected<T, E> with a type for the E parameter that is not a valid template argument for unexpected is ill-formed.

3 When T is not cv void, it shall meet the Cpp17Destructible requirements (Table 35). E shall meet the Cpp17Destructible requirements.

22.8.6.2 Constructors

The exposition-only variable template converts-from-any-cvref defined in 22.5.3.2 is used by some constructors for expected.

constexpr expected();
1 Constraints: is_default_constructible_v<T> is true.
2 Effects: Value-initializes val.
3 Postconditions: has_value() is true.
4 Throws: Any exception thrown by the initialization of val.

constexpr expected(const expected& rhs);
6 Effects: If rhs.has_value() is true, direct-non-list-initializes val with *rhs. Otherwise, direct-non-list-initializes unex with rhs.error().
7 Postconditions: rhs.has_value() == this->has_value().
8 Throws: Any exception thrown by the initialization of val or unex.
9 Remarks: This constructor is defined as deleted unless
(9.1) — is_copy_constructible_v<T> is true and
(9.2) — is_copy_constructible_v<E> is true.
10
This constructor is trivial if
(10.1) — is_trivially_copy_constructible_v<T> is true and
(10.2) — is_trivially_copy_constructible_v<E> is true.

constexpr expected(expected&& rhs) noexcept;
11 Constraints:
(11.1) — is_move_constructible_v<T> is true and
(11.2) — is_move_constructible_v<E> is true.
12 Effects: If rhs.has_value() is true, direct-non-list-initializes val with std::move(*rhs). Otherwise, direct-non-list-initializes unex with std::move(rhs.error()).
13 Postconditions: rhs.has_value() is unchanged; rhs.has_value() == this->has_value() is true.
14 Throws: Any exception thrown by the initialization of val or unex.
15 Remarks: The exception specification is equivalent to is_nothrow_move_constructible_v<T> && is_nothrow_move_constructible_v<E>.
16 This constructor is trivial if
(16.1) — is_trivially_move_constructible_v<T> is true and
(16.2) — is_trivially_move_constructible_v<E> is true.

template<class U, class G>
constexpr explicit(see below) expected(const expected<U, G>& rhs);

Let:
— UF be const U& for the first overload and U for the second overload.
— GF be const G& for the first overload and G for the second overload.

Constraints:
— is_constructible_v<T, UF> is true; and
— is_constructible_v<E, GF> is true; and
— if T is not cv bool, converts-from-any-cvref<T, expected<U, G>> is false; and
— is_constructible_v<unexpected<E>, expected<U, G>&> is false; and
— is_constructible_v<unexpected<E>, const expected<U, G>&> is false; and
— is_constructible_v<unexpected<E>, const expected<U, G>> is false.

Effects: If rhs.has_value(), direct-non-list-initializes val with std::forward<UF>(*rhs). Otherwise, direct-non-list-initializes unex with std::forward<GF>(rhs.error()).
Postconditions: rhs.has_value() is unchanged; rhs.has_value() == this->has_value() is true.
Throws: Any exception thrown by the initialization of val or unex.
Remarks: The expression inside explicit is equivalent to !is_convertible_v<UF, T> || !is_convertible_v<GF, E>.

template<class U = T>
constexpr explicit(!is_convertible_v<U, T>) expected(U&& v);
Constrains:
— is_same_v<remove_cvref_t<U>, in_place_t> is false; and
— is_same_v<expected, remove_cvref_t<T>> is false; and
— remove_cvref_t<T> is not a specialization of unexpected; and
— is_constructible_v<T, U> is true; and
— if T is cv bool, remove_cvref_t<T> is not a specialization of expected.
Effects: Direct-non-list-initializes val with std::forward<T>(v).
Postconditions: has_value() is true.
Throws: Any exception thrown by the initialization of val.

Let GF be const G& for the first overload and G for the second overload.
Constraints: is_constructible_v<E, GF> is true.
Effects: Direct-non-list-initializes unex with std::forward<GF>(e.error()).
Postconditions: has_value() is false.
Throws: Any exception thrown by the initialization of unex.

template<class... Args>
constexpr explicit expected(in_place_t, Args&&... args);
Constraints: is_constructible_v<T, Args...> is true.
Effects: Direct-non-list-initializes val with std::forward<Args>(args)....
Postconditions: has_value() is true.
Throws: Any exception thrown by the initialization of val.

template<class U, class... Args>
constexpr explicit expected(in_place_t, initializer_list<U> il, Args&&... args);
Constraints: is_constructible_v<T, initializer_list<U> il, Args...> is true.
Effects: Direct-non-list-initializes \texttt{val} with \texttt{il}, \texttt{std::forward<Args>(args)}....

Postconditions: \texttt{has_value()} is true.

Throws: Any exception thrown by the initialization of \texttt{val}.

\begin{verbatim}
template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);
\end{verbatim}

Effects: Direct-non-list-initializes \texttt{unex} with \texttt{std::forward<Args>(args)}....

Postconditions: \texttt{has_value()} is false.

Throws: Any exception thrown by the initialization of \texttt{unex}.

\begin{verbatim}
template<class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
\end{verbatim}

Effects: Direct-non-list-initializes \texttt{unex} with \texttt{il}, \texttt{std::forward<Args>(args)}....

Postconditions: \texttt{has_value()} is false.

Throws: Any exception thrown by the initialization of \texttt{unex}.

22.8.6.3 Destructor

\begin{verbatim}
constexpr ~expected();
\end{verbatim}

Effects: If \texttt{has_value()} is true, destroys \texttt{val}, otherwise destroys \texttt{unex}.

Remarks: If \texttt{is_trivially_destructible_v<T>} is true, and \texttt{is_trivially_destructible_v<E>} is true, then this destructor is a trivial destructor.

22.8.6.4 Assignment

This subclause makes use of the following exposition-only function template:

\begin{verbatim}
template<class T, class U, class... Args>
constexpr void reinit-expected(T& newval, U& oldval, Args&&... args) {
  // exposition only
  if constexpr (is_nothrow_constructible_v<T, Args...>) {
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::forward<Args>(args)...);
  } else if constexpr (is_nothrow_move_constructible_v<T>) {
    T tmp(std::forward<Args>(args)...);
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::move(tmp));
  } else {
    U tmp(std::move(oldval));
    destroy_at(addressof(oldval));
    try {
      construct_at(addressof(newval), std::forward<Args>(args)...);
    } catch (...) {
      construct_at(addressof(oldval), std::move(tmp));
      throw;
    }
  }
}
\end{verbatim}

constexpr expected& operator=(const expected& rhs);

Effects:

(2.1) If \texttt{this->has_value()} \&\& \texttt{rhs.has_value()} is true, equivalent to \texttt{val = *rhs}.

(2.2) Otherwise, if \texttt{this->has_value()} is true, equivalent to:
\begin{verbatim}
reinit-expected(unex, val, rhs.error())
\end{verbatim}

(2.3) Otherwise, if \texttt{rhs.has_value()} is true, equivalent to:
\begin{verbatim}
reinit-expected(val, unex, *rhs)
\end{verbatim}
(2.4) Otherwise, equivalent to \texttt{unex = rhs.error()}. Then, if no exception was thrown, equivalent to: \texttt{has_val = rhs.has_value(); return *this;}

\textbf{Returns:} \texttt{*this.}

\textbf{Remarks:} This operator is defined as deleted unless:

(4.1) \texttt{is\_copy\_assignable\_v<T> is true and}

(4.2) \texttt{is\_copy\_constructible\_v<T> is true and}

(4.3) \texttt{is\_copy\_assignable\_v<E> is true and}

(4.4) \texttt{is\_copy\_constructible\_v<E> is true and}

(4.5) \texttt{is\_nothrow\_move\_constructible\_v<T> || is\_nothrow\_move\_constructible\_v<E> is true.}

\texttt{constexpr expected& operator=(expected&& rhs) noexcept (see below);}

\textbf{Constraints:}

(5.1) \texttt{is\_move\_constructible\_v<T> is true and}

(5.2) \texttt{is\_move\_assignable\_v<T> is true and}

(5.3) \texttt{is\_move\_constructible\_v<E> is true and}

(5.4) \texttt{is\_move\_assignable\_v<E> is true and}

(5.5) \texttt{is\_nothrow\_move\_constructible\_v<T> || is\_nothrow\_move\_constructible\_v<E> is true.}

\textbf{Effects:}

(6.1) If \texttt{this->has\_value() && rhs.has\_value()} is true, equivalent to \texttt{val = std::move(*rhs)}.

(6.2) Otherwise, if \texttt{this->has\_value()} is true, equivalent to:

\texttt{reinit\_expected(unex, val, std::move(rhs.error()))}

(6.3) Otherwise, if \texttt{rhs.has\_value()} is true, equivalent to:

\texttt{reinit\_expected(val, unex, std::move(*rhs))}

(6.4) Otherwise, equivalent to \texttt{unex = std::move(rhs.error())}.

Then, if no exception was thrown, equivalent to: \texttt{has_val = rhs.has_value(); return *this;}

\textbf{Returns:} \texttt{*this.}

\textbf{Remarks:} The exception specification is equivalent to:

\texttt{is\_nothrow\_move\_assignable\_v<T> && is\_nothrow\_move\_constructible\_v<T> &&}

\texttt{is\_nothrow\_move\_assignable\_v<E> && is\_nothrow\_move\_constructible\_v<E>}

\texttt{template<class U = T> constexpr expected& operator=(U& v);}

\textbf{Constraints:}

(9.1) \texttt{is\_same\_v<expected, remove\_cvref\_t<U>> is false; and}

(9.2) \texttt{remove\_cvref\_t<U> is not a specialization of unexpected; and}

(9.3) \texttt{is\_constructible\_v<T, U> is true; and}

(9.4) \texttt{is\_assignable\_v<T& , U> is true; and}

(9.5) \texttt{is\_nothrow\_move\_constructible\_v<T, U> || is\_nothrow\_move\_constructible\_v<T> ||}

\texttt{is\_nothrow\_move\_constructible\_v<E> is true.}

\textbf{Effects:}

(10.1) If \texttt{has\_value()} is true, equivalent to: \texttt{val = std::forward<U>(v);}

(10.2) Otherwise, equivalent to:

\texttt{reinit\_expected(val, unex, std::forward<U>(v));

\texttt{has\_val = true;}}

\textbf{Returns:} \texttt{*this.}
template<class G>
constexpr expected& operator=(const unexpected<G>& e);

template<class G>
constexpr expected& operator=(unexpected<G>&& e);

Let GF be const G& for the first overload and G for the second overload.

Constraints:

(13.1) is_constructible_v<E, GF> is true; and
(13.2) is_assignable_v<E&, GF> is true; and
(13.3) is_nothrow_constructible_v<E, GF> || is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E> is true.

Effects:

(14.1) If has_value() is true, equivalent to:

reinit-expected(unex, val, std::forward<GF>(e.error()));

has_val = false;

(14.2) Otherwise, equivalent to: unex = std::forward<GF>(e.error());

Returns: *this.

template<class... Args>
constexpr T& emplace(Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, Args...> is true.

Effects: Equivalent to:

if (has_value()) {
    destroy_at(addressof(val));
} else {
    destroy_at(addressof(unex));
    has_val = true;
}

return *construct_at(addressof(val), std::forward<Args>(args)...);

template<class U, class... Args>
constexpr T& emplace(initializer_list<U> il, Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Equivalent to:

if (has_value()) {
    destroy_at(addressof(val));
} else {
    destroy_at(addressof(unex));
    has_val = true;
}

return *construct_at(addressof(val), il, std::forward<Args>(args)...);

22.8.6.5 Swap [expected.object.swap]

constexpr void swap(expected& rhs) noexcept(see below);

Constraints:

(1.1) is_swappable_v<T> is true and
(1.2) is_swappable_v<E> is true and
(1.3) is_move_constructible_v<T> && is_move_constructible_v<E> is true, and
(1.4) is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E> is true.

Effects: See Table 63.

For the case where rhs.has_value() is false and this->has_value() is true, equivalent to:

if constexpr (is_nothrow_move_constructible_v<E>) {
    E tmp(std::move(rhs.unex));
}
Table 63 — swap(expected&) effects  

<table>
<thead>
<tr>
<th>this-&gt;has_value()</th>
<th>!this-&gt;has_value()</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rhs.has_value()</strong></td>
<td>equivalent to: using std::swap; swap(val, rhs.val);</td>
</tr>
<tr>
<td><strong>!rhs.has_value()</strong></td>
<td>see below</td>
</tr>
</tbody>
</table>

```cpp
destroy_at(addressof(rhs.unez));
try {
    construct_at(addressof(rhs.val), std::move(val));
    destroy_at(addressof(val));
    construct_at(addressof(unez), std::move(tmp));
} catch (...) {
    construct_at(addressof(rhs.unez), std::move(tmp));
    throw;
}
} else {
    T tmp(std::move(val));
    destroy_at(addressof(val));
    try {
        construct_at(addressof(unez), std::move(tmp));
        construct_at(addressof(rhs.val), std::move(tmp));
    } catch (...) {
        construct_at(addressof(val), std::move(tmp));
        throw;
    }
    has_val = false;
    rhs.has_val = true;
}
```

**Throws:** Any exception thrown by the expressions in the Effects.

**Remarks:** The exception specification is equivalent to:

```cpp
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> &&
is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>
```

```
fRIEND constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));
```

**Effects:** Equivalent to `x.swap(y)`.

### 22.8.6.6 Observers

```cpp
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

**Preconditions:** `has_value()` is true.

**Returns:** `addressof(val)`.

```cpp
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
```

**Preconditions:** `has_value()` is true.

**Returns:** `val`.

```cpp
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
```

**Preconditions:** `has_value()` is true.

**Returns:** `std::move(val)`.

---

© ISO/IEC N4971
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;

Returns: has_val.

constexpr const T& value() const &;
constexpr T& value() &;

Mandates: is_copy_constructible_v<E> is true.
Returns: val, if has_value() is true.
Throws: bad_expected_access(as_const(error())) if has_value() is false.

constexpr T&& value() &&;
constexpr const T&& value() const &&;

Mandates: is_copy_constructible_v<E> is true and is_constructible_v<E, decltype(std::move(error()))> is true.
Returns: std::move(val), if has_value() is true.
Throws: bad_expected_access(std::move(error())) if has_value() is false.

constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;

Preconditions: has_value() is false.
Returns: unex.

constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;

Preconditions: has_value() is false.
Returns: std::move(unex).

template<class U> constexpr T value_or(U&& v) const &;

Mandates: is_copy_constructible_v<T> is true and is_convertible_v<U, T> is true.
Returns: has_value() ? **this : static_cast<T>(std::forward<U>(v)).

template<class U> constexpr T value_or(U&& v) &&;

Mandates: is_move_constructible_v<T> is true and is_convertible_v<U, T> is true.
Returns: has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v)).

template<class G = E> constexpr E error_or(G&& e) const &;

Mandates: is_copy_constructible_v<E> is true and is_constructible_v<E, decltype(error())> is true.
Returns: std::forward<G>(e) if has_value() is true, error() otherwise.

template<class G = E> constexpr E error_or(G&& e) &&;

Mandates: is_move_constructible_v<E> is true and is_constructible_v<E, decltype(error())> is true.
Returns: std::forward<E>(e) if has_value() is true, std::move(error()) otherwise.

22.8.6.7 Monadic operations

Let U be remove_cvref_t<invoke_result_t<F& f, decltype((val))>>.

Constraints: is_constructible_v<E, decltype(error())> is true.

Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.

Effects: Equivalent to:
if (has_value())
    return invoke(std::forward<F>(f), val);

§ 22.8.6.7
else
  return U(unexpect, error());

template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;

Let U be remove_cvref_t<invoke_result_t<F, decltype(std::move(val))>>.

Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.

Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.

Effects: Equivalent to:
  if (has_value())
    return invoke(std::forward<F>(f), std::move(val));
  else
    return U(unexpect, std::move(error()));

template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;

Let G be remove_cvref_t<invoke_result_t<F, decltype(error())>>.

Constraints: is_constructible_v<T, decltype((val))> is true.

Mandates: G is a specialization of expected and is_same_v<G::value_type, T> is true.

Effects: Equivalent to:
  if (has_value())
    return G(in_place, val);
  else
    return invoke(std::forward<F>(f), error());

template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;

Let G be remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>.

Constraints: is_constructible_v<T, decltype(std::move(val))> is true.

Mandates: G is a specialization of expected and is_same_v<G::value_type, T> is true.

Effects: Equivalent to:
  if (has_value())
    return G(in_place, std::move(val));
  else
    return invoke(std::forward<F>(f), std::move(error()));

template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;

Let U be remove_cv_t<invoke_result_t<F, decltype(std::move(val))>>.

Constraints: is_constructible_v<E, decltype(error())> is true.

Mandates: U is a valid value type for expected. If is_void_v<U> is false, the declaration
  U u(invoke(std::forward<F>(f), val));

is well-formed.

Effects:
  — If has_value() is false, returns expected<U, E>(unexpect, error()).
  — Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member
    is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f), val).
  — Otherwise, evaluates invoke(std::forward<F>(f), val) and then returns expected<U, E>().

template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;

Let U be remove_cv_t<invoke_result_t<F, decltype(std::move(val))>>.

Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.
Mandates: U is a valid value type for expected. If is_void_v<U> is false, the declaration

\[
U u(\text{invoke}(\text{std::forward<F>(f), std::move(val)}));
\]

is well-formed.

Effects:

(24.1) If has_value() is false, returns expected<U, E>(unexpect, std::move(error())).

(24.2) Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f), std::move(val)).

(24.3) Otherwise, evaluates invoke(std::forward<F>(f), std::move(val)) and then returns expected<U, E>().

\[
\text{template<class F> constexpr auto transform_error(F&& f) &;}\]
\[
\text{template<class F> constexpr auto transform_error(F&& f) const &;}\]

Let G be remove_cv_t<\text{invoke_result_t<F, decltype(error())>>.}

Constraints: is_constructible_v<T, decltype((val))> is true.

Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration

\[
G g(\text{invoke}(\text{std::forward<F>(f), error()}));
\]

is well-formed.

Returns: If has_value() is true, expected<T, G>(in_place, std::move(val)); otherwise, an expected<T, G> object whose has_val member is false and unex member is direct-non-list-initialized with invoke(std::forward<F>(f), std::move(error())).

\[
\text{template<class F> constexpr auto transform_error(F&& f) &;}\]
\[
\text{template<class F> constexpr auto transform_error(F&& f) const &;}\]

Let G be remove_cv_t<\text{invoke_result_t<F, decltype(std::move(error()))>>.}

Constraints: is_constructible_v<T, decltype(std::move(val))> is true.

Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration

\[
G g(\text{invoke}(\text{std::forward<F>(f), std::move(error())});
\]

is well-formed.

Returns: If has_value() is true, expected<T, G>(in_place, std::move(val)); otherwise, an expected<T, G> object whose has_val member is false and unex member is direct-non-list-initialized with invoke(std::forward<F>(f), std::move(error())).

22.8.6.8 Equality operators [expected.object.eq]

\[
\text{template<class T2, class E2> requires (!is_void_v<T2>>}
\]

\[
\text{friend constexpr bool operator==(const expected&lt;T2, E2&gt;& y);}\]

Mandates: The expressions \(\neg x == \neg y\) and \(x\text{.error}() == y\text{.error}()\) are well-formed and their results are convertible to bool.

Returns: If \(x\text{.has_value}()\) does not equal \(y\text{.has_value}(), false; otherwise if \(x\text{.has_value}()\) is true, \(\neg x == \neg y\); otherwise \(x\text{.error}() == y\text{.error}().

\[
\text{template<class T2> friend constexpr bool operator==(const expected&lt;T2, E2&gt;& y);}\]

Mandates: The expression \(\neg x == \neg y\) is well-formed and its result is convertible to bool.

[Note 1: T need not be Cpp17EqualityComparable. — end note]

Returns: \(x\text{.has_value}() \&\& \text{static_cast&lt;bool&gt;}(*x == y).\)

\[
\text{template&lt;class E2&gt; friend constexpr bool operator==(const expected&lt;E2&gt;& e);}\]

Mandates: The expression \(x\text{.error}() == e\text{.error}()\) is well-formed and its result is convertible to bool.

Returns: \(!x\text{.has_value}() \&\& \text{static_cast&lt;bool&gt;}(x\text{.error}() == e\text{.error}()).\)
22.8.7 Partial specialization of expected for void types

22.8.7.1 General

template<class T, class E> requires is_void_v<T>
class expected<T, E> {
  public:
    using value_type = T;
    using error_type = E;
    using unexpected_type = unexpected<E>;

    template<class U>
    using rebind = expected<U, error_type>;

    friend constexpr void swap(expected& x, expected& y) noexcept;

    // 22.8.7.6, observers
    constexpr explicit operator bool() const noexcept;
    constexpr bool has_value() const noexcept;
    constexpr void operator*() const noexcept;
    constexpr void value() const &; // freestanding-deleted
    constexpr void value() &&; // freestanding-deleted
    constexpr const E& error() const & noexcept;
    constexpr E& error() & noexcept;
    constexpr const E&& error() const && noexcept;
    constexpr E&& error() && noexcept;
    template<class G = E>
    constexpr E error_or(G&&) const &;
    template<class G = E>
    constexpr E error_or(G&&) &&;
// 22.8.7.7, monadic operations

```c++
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &;
template<class F> constexpr auto or_else(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &;
template<class F> constexpr auto transform_error(F&& f) const &&;
```

// 22.8.7.8, equality operators

```c++
template<class T2, class E2> requires is_void_v<T2>
friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
template<class E2>
friend constexpr bool operator==(const expected&, const unexpected<E2>&);
```

private:

```c++
bool has_val;       // exposition only
union {
    E unex;        // exposition only
};
```

1. Any object of type `expected<T, E>` either represents a value of type `T`, or contains a value of type `E` within its own storage. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the object of type `E`. Member `has_val` indicates whether the `expected<T, E>` object represents a value of type `T`.

2. A program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

3. `E` shall meet the requirements of `Cpp17Destructible` (Table 35).

### 22.8.7.2 Constructors

```c++
constexpr expected() noexcept;
```

**Postconditions**: `has_value()` is true.

```c++
constexpr expected(const expected& rhs);
```

**Effects**: If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `rhs.error()`.

**Postconditions**: `rhs.has_value()` == `this->has_value()`.

**Throws**: Any exception thrown by the initialization of `unex`.

**Remarks**: This constructor is defined as deleted unless `is_copy_constructible_v<E>` is true.

This constructor is trivial if `is_trivially_copy_constructible_v<E>` is true.

```c++
constexpr expected(expected&& rhs) noexcept(is_nothrow_move_constructible_v<E>);
```

**Constraints**: `is_move_constructible_v<E>` is true.

**Effects**: If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `std::move(rhs.error())`.

**Postconditions**: `rhs.has_value()` is unchanged; `rhs.has_value()` == `this->has_value()` is true.

**Throws**: Any exception thrown by the initialization of `unex`.

**Remarks**: This constructor is trivial if `is_trivially_move_constructible_v<E>` is true.
template<class U, class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const expected<U, G>& rhs);

Let GF be const G& for the first overload and G for the second overload.

Constraints:
(13.1) — is_void_v<U> is true; and
(13.2) — is_constructible_v<E, GF> is true; and
(13.3) — is_constructible_v<unexpected<E>, expected<U, G>&> is false; and
(13.4) — is_constructible_v<unexpected<E>, expected<U, G>> is false; and
(13.5) — is_constructible_v<unexpected<E>, const expected<U, G>&> is false; and
(13.6) — is_constructible_v<unexpected<E>, const expected<U, G>> is false.

Effects: If rhs.has_value() is false, direct-non-list-initializes unex with std::forward<GF>(rhs.error()).

Postconditions: rhs.has_value() is unchanged; rhs.has_value() == this->has_value() is true.

Throws: Any exception thrown by the initialization of unex.

template<class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);

Let GF be const G& for the first overload and G for the second overload.

Constraints: is_constructible_v<E, GF> is true.

Effects: Direct-non-list-initializes unex with std::forward<GF>(e.error()).

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

castexpr explicit expected(in_place_t) noexcept;

Postconditions: has_value() is true.

template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);

Constraints: is_constructible_v<E, Args...> is true.

Effects: Direct-non-list-initializes unex with std::forward<Args>(args)....

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

template<class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<E, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes unex with il, std::forward<Args>(args)....

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

22.8.7.3 Destructor
[expected.void.dtor]

castexpr ~expected();

Effects: If has_value() is false, destroys unex.

Remarks: If is_trivially_destructible_v<E> is true, then this destructor is a trivial destructor.

22.8.7.4 Assignment
[expected.void.assign]
constexpr expected& operator=(const expected& rhs);

Effects:
1. If this->has_value() && rhs.has_value() is true, no effects.
2. Otherwise, if this->has_value() is true, equivalent to: construct_addressof(unex, rhs.unex); has_val = false;
3. Otherwise, if rhs.has_value() is true, destroys unex and sets has_val to true.
4. Otherwise, equivalent to unex = rhs.error().

Returns: *this.

Remarks: This operator is defined as deleted unless is_copy_assignable_v<E> is true and is_copy_constructible_v<E> is true.

castexpr expected& operator=(expected&& rhs) noexcept(see below);

Effects:
1. If this->has_value() && rhs.has_value() is true, no effects.
2. Otherwise, if this->has_value() is true, equivalent to:
   construct_addressof(unex, std::move(rhs.unex));
   has_val = false;
3. Otherwise, if rhs.has_value() is true, destroys unex and sets has_val to true.
4. Otherwise, equivalent to unex = std::move(rhs.error()).

Returns: *this.

Remarks: The exception specification is equivalent to is_nothrow_move_constructible_v<E> && is_nothrow_move_assignable_v<E>.

This operator is defined as deleted unless is_move_constructible_v<E> is true and is_move_assignable_v<E> is true.

template<class G>
castexpr expected& operator=(const unexpected<G>& e);
template<class G>
castexpr expected& operator=(unexpected<G>&& e);

Let GF be const G& for the first overload and G for the second overload.

Constraints: is_constructible_v<E, GF> is true and is_assignable_v<E&, GF> is true.

Effects:
1. If has_value() is true, equivalent to:
   construct_addressof(unex, std::forward<GF>(e.error()));
   has_val = false;
2. Otherwise, equivalent to: unex = std::forward<GF>(e.error());

Returns: *this.

castexpr void emplace() noexcept;

Effects: If has_value() is false, destroys unex and sets has_val to true.

22.8.7.5 Swap [expected.void.swap]

castexpr void swap(expected& rhs) noexcept(see below);

Constraints: is_swappable_v<E> is true and is_move_constructible_v<E> is true.

Effects: See Table 64.

For the case where rhs.has_value() is false and this->has_value() is true, equivalent to:
construct_addressof(unex, std::move(rhs.unex));
destroy_addressof(rhs.unex);
has_val = false;
rhs.has_val = true;
### Table 64 — swap(expected&) effects

<table>
<thead>
<tr>
<th>this-&gt;has_value()</th>
<th>!this-&gt;has_value()</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs.has_value()</td>
<td>no effects</td>
</tr>
<tr>
<td>!rhs.has_value()</td>
<td>see below</td>
</tr>
<tr>
<td>calls rhs.swap(*this)</td>
<td>equivalent to: using std::swap; swap(unex, rhs.unex);</td>
</tr>
</tbody>
</table>

3. **Throws**: Any exception thrown by the expressions in the *Effects*.

4. **Remarks**: The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>`.

friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));

Effects: Equivalent to `x.swap(y)`.

#### 22.8.7.6 Observers

```cpp
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
```

1. **Returns**: `has_value`

```cpp
constexpr void operator*() const noexcept;
```

2. **Preconditions**: `has_value()` is true.

```cpp
constexpr void value() const &;
```

3. **Mandates**: `is_copy_constructible_v<E>` is true.

```cpp
Throws: bad_expected_access(error()) if has_value() is false.
```

```cpp
constexpr void value() &&;
```

4. **Mandates**: `is_copy_constructible_v<E>` is true and `is_move_constructible_v<E>` is true.

```cpp
Throws: bad_expected_access(std::move(error())) if has_value() is false.
```

```cpp
constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
```

7. **Preconditions**: `has_value()` is false.

```cpp
constexpr E&& error() && noexcept;
```

10. **Preconditions**: `has_value()` is false.

```cpp
template<class G = E> constexpr E error_or(G&& e) const &;
```

13. **Mandates**: `is_move_constructible_v<E>` is true and `is_convertible_v<G, E>` is true.

```cpp
template<class G = E> constexpr E error_or(G&& e) &&;
```

16. **Mandates**: `is_convertible_v<G, E>` is true.

#### 22.8.7.7 Monadic operations

```cpp
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

1. **Let U be remove_cvref_t<invoke_result_t<F>>.**

2. **Constraints**: `is_convertible_v<E, decltype(error())>` is true.
Mandates: U is a specialization of expected and is_same_v< U::error_type, E > is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return invoke(std::forward<F>(f));
else
    return U(unexpect, error());
```

```cpp
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let U be remove_cvref_t<invoke_result_t<F>>.

Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.

Mandates: U is a specialization of expected and is_same_v< U::error_type, E > is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return invoke(std::forward<F>(f));
else
    return U(unexpect, std::move(error()));
```

```cpp
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;
```

Let G be remove_cvref_t<invoke_result_t<F, decltype(error())>>.

Mandates: G is a specialization of expected and is_same_v< G::value_type, T > is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return G();
else
    return invoke(std::forward<F>(f), error());
```

```cpp
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

Let G be remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>.

Mandates: G is a specialization of expected and is_same_v< G::value_type, T > is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return G();
else
    return invoke(std::forward<F>(f), std::move(error()));
```

```cpp
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

Let U be remove_cv_t<invoke_result_t<F>>.

Constraints: is_constructible_v<E, decltype(error())> is true.

Mandates: U is a valid value type for expected. If is_void_v<U> is false, the declaration

U u(invoke(std::forward<F>(f)));

is well-formed.

Effects:

18.1 If has_value() is false, returns expected<U, E>(unexpect, error()).

18.2 Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member

is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f)).

18.3 Otherwise, evaluates invoke(std::forward<F>(f)) and then returns expected<U, E>().

```cpp
template<class F> constexpr auto transform(F&& f) &&;
```
template<class F> constexpr auto transform(F&& f) const &&;

Let \( U \) be `remove_cv_t<\text{invoke\_result\_t<F>>}`.

Constraints: `is\_constructible_v<E, decltype(std::move(error()))>` is true.

Mandates: \( U \) is a valid value type for `expected`. If `is\_void_v<\mathbb{U}>` is false, the declaration

\[
U \ u(\text{invoke}(\text{std::forward\<\(F\)>(f)}));
\]

is well-formed.

Effects:

(22.1) — If `has\_value()` is false, returns `expected<\mathbb{U}, E>(\text{unexpect}, \text{std::move\(\)\(error()\))}`.

(22.2) — Otherwise, if `is\_void_v<\mathbb{U}>` is false, returns an `expected<\mathbb{U}, E>` object whose `has\_val` member is true and `val` member is direct-non-list-initialized with `\text{invoke}(\text{std::forward\<\(F\)>(f)}).

(22.3) — Otherwise, evaluates `\text{invoke}(\text{std::forward\<\(F\)>(f)) and then returns `expected<\mathbb{U}, E>()`.}

template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;

Let \( G \) be `remove_cv_t<\text{invoke\_result\_t<F, decltype(error())}}>>.`

Mandates: \( G \) is a valid template argument for `unexpected (22.8.3.1)` and the declaration

\[
G \ g(\text{invoke}(\text{std::forward\<\(F\)>(f), error()}));
\]

is well-formed.

Returns: If `has\_value()` is true, `expected\<\mathbb{T}, G>()`; otherwise, an `expected\<\mathbb{T}, G>` object whose `has\_val` member is false and `unex` member is direct-non-list-initialized with `\text{invoke}(\text{std::forward\<\(F\)>(f), std::move(error()))}.

22.9 Bitsets

22.9.1 Header <bitset> synopsis

The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.
```cpp
#include <string>  // see 23.4.2
#include <iosfwd>  // for istream (31.7.1), ostream (31.7.2), see 31.3.1

namespace std {
    template<size_t N> class bitset;

    // 22.9.4, bitset operators
    template<size_t N>
    constexpr bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
    constexpr bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
    constexpr bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
    template<class charT, class traits, size_t N>
    basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
    template<class charT, class traits, size_t N>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}
```

### 22.9.2 Class template bitset

#### 22.9.2.1 General

```cpp
namespace std {
    template<size_t N> class bitset {
        public:
            // bit reference
            class reference {
                friend class bitset;
                constexpr reference() noexcept;
                constexpr reference(const reference&) = default;
                constexpr ~reference();
                constexpr reference& operator=(bool x) noexcept;  // for b[i] = x;
                constexpr reference& operator=(const reference&) noexcept;  // for b[i] = b[j];
                constexpr bool operator~() const noexcept;  // flips the bit
                constexpr reference& flip() noexcept;  // for b[i].flip();
            };

        // 22.9.2.2, constructors
        constexpr bitset() noexcept;
        constexpr bitset(unsigned long long val) noexcept;
        template<class charT, class traits, class Allocator>
        constexpr explicit bitset(  
            const basic_string<charT, traits, Allocator>& str,
            typename basic_string<charT, traits, Allocator>::size_type pos = 0,
            typename basic_string<charT, traits, Allocator>::size_type n
                = basic_string<charT, traits, Allocator>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));
        template<class charT, class traits>
        constexpr explicit bitset(  
            basic_string_view<charT, traits> str,
            typename basic_string_view<charT, traits>::size_type pos = 0,
            typename basic_string_view<charT, traits>::size_type n
                = basic_string_view<charT, traits>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));
    }
```
The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, N.

Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in 22.9.2 can report three kinds of errors, each associated with a distinct exception:

1. an *invalid-argument* error is associated with exceptions of type `invalid_argument` (19.2.5);  
2. an *out-of-range* error is associated with exceptions of type `out_of_range` (19.2.7);  
3. an *overflow* error is associated with exceptions of type `overflow_error` (19.2.10).  

---

1. Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

2. The functions described in 22.9.2 can report three kinds of errors, each associated with a distinct exception:

- an *invalid-argument* error is associated with exceptions of type `invalid_argument` (19.2.5);  
- an *out-of-range* error is associated with exceptions of type `out_of_range` (19.2.7);  
- an *overflow* error is associated with exceptions of type `overflow_error` (19.2.10).
22.9.2.2 Constructors

```cpp
constexpr bitset() noexcept;
```

**Effects:** Initializes all bits in \*this to zero.

```cpp
constexpr bitset(unsigned long long val) noexcept;
```

**Effects:** Initializes the first \(M\) bit positions to the corresponding bit values in \(\text{val}\). \(M\) is the smaller of \(N\) and the number of bits in the value representation (6.8.1) of unsigned long long. If \(M < N\), the remaining bit positions are initialized to zero.

```cpp
template<class charT, class traits, class Allocator>
constexpr explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

**Effects:** Determines the effective length \(rlen\) of the initializing string as the smaller of \(n\) and \(\text{str.size() - pos}\). Initializes the first \(M\) bit positions to values determined from the corresponding characters in the string \(\text{str}\). \(M\) is the smaller of \(N\) and \(rlen\).

An element of the constructed object has value zero if the corresponding character in \(\text{str}\), beginning at position \(\text{pos}\), is \(\text{zero}\). Otherwise, the element has the value one. Character position \(\text{pos} + M - 1\) corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

If \(M < N\), remaining bit positions are initialized to zero.

The function uses \(\text{traits::eq}\) to compare the character values.

```cpp
tostring<charT if \(\text{pos > str.size()}\) or invalid_argument if any of the \(rlen\) characters in \(\text{str}\) beginning at position \(\text{pos}\) is other than \(\text{zero}\) or \(\text{one}\).
```

```cpp
template<class charT>
constexpr explicit bitset(
    const charT* str,
    typename basic_string_view<charT>::size_type n = basic_string_view<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

**Effects:** As if by:

```cpp
bitset(n == basic_string_view<charT>::npos ? basic_string_view<charT>(str) : basic_string_view<charT>(str, n), 0, n, zero, one)
```

22.9.2.3 Members

```cpp
constexpr bitset& operator&=(const bitset& rhs) noexcept;
```

**Effects:** Clears each bit in \*this for which the corresponding bit in \(\text{rhs}\) is clear, and leaves all other bits unchanged.

**Returns:** \*this.
constexpr bitset\& operator\|=\!(const\ bitset\& rhs) noexcept;

**Effects:** Sets each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

**Returns:** *this.

constexpr bitset\& operator\^-\!(const\ bitset\& rhs) noexcept;

**Effects:** Toggles each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

**Returns:** *this.

constexpr bitset\& operator\<<\!(size_t pos) noexcept;

**Effects:** Replaces each bit at position I in *this with a value determined as follows:

1. If I < pos, the new value is zero;
2. If I >= pos, the new value is the previous value of the bit at position I - pos.

**Returns:** *this.

constexpr bitset\& operator\>>\!(size_t pos) noexcept;

**Effects:** Replaces each bit at position I in *this with a value determined as follows:

1. If pos >= N - I, the new value is zero;
2. If pos < N - I, the new value is the previous value of the bit at position I + pos.

**Returns:** *this.

constexpr bitset\& operator\<<(size_t pos) const noexcept;

**Returns:** bitset(*this) <<= pos.

constexpr bitset\& operator\>>(size_t pos) const noexcept;

**Returns:** bitset(*this) >>= pos.

constexpr bitset\& set() noexcept;

**Effects:** Sets all bits in *this.

**Returns:** *this.

constexpr bitset\& set(size_t pos, bool val = true);

**Effects:** Stores a new value in the bit at position pos in *this. If val is true, the stored value is one, otherwise it is zero.

**Returns:** *this.

**Throws:** out_of_range if pos does not correspond to a valid bit position.

constexpr bitset\& reset() noexcept;

**Effects:** Resets all bits in *this.

**Returns:** *this.

constexpr bitset\& reset(size_t pos);

**Effects:** Resets the bit at position pos in *this.

**Returns:** *this.

**Throws:** out_of_range if pos does not correspond to a valid bit position.

constexpr bitset operator\~-\!(\!const) noexcept;

**Effects:** Constructs an object x of class bitset and initializes it with *this.

**Returns:** x.flip().

constexpr bitset\& flip() noexcept;

**Effects:** Toggles all bits in *this.
Returns: *this.

constexpr bitset& flip(size_t pos);

Effects: Toggles the bit at position pos in *this.

Returns: *this.

Throws: out_of_range if pos does not correspond to a valid bit position.

constexpr bool operator[](size_t pos) const;

Preconditions: pos is valid.

Returns: true if the bit at position pos in *this has the value one, otherwise false.

Throws: Nothing.

constexpr bitset::reference operator[](size_t pos);

Preconditions: pos is valid.

Returns: An object of type bitset::reference such that (*this)[pos] == this->test(pos), and such that (*this)[pos] = val is equivalent to this->set(pos, val).

Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.9.2), any access or update through the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.

constexpr unsigned long to_ulong() const;

Returns: x.

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long.

constexpr unsigned long long to_ullong() const;

Returns: x.

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long long.

template<class charT = char,
class traits = char_traits<charT>,
class Allocator = allocator<charT>>
constexpr basic_string<charT, traits, Allocator> to_string(charT zero = charT('0'), charT one = charT('1')) const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length N characters. Each character is determined by the value of its corresponding bit position in *this. Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes the character one.

Returns: The created object.

constexpr size_t count() const noexcept;

Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

Returns: N.

constexpr bool operator==(const bitset& rhs) const noexcept;

Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

constexpr bool test(size_t pos) const;

Returns: true if the bit at position pos in *this has the value one.

Throws: out_of_range if pos does not correspond to a valid bit position.
constexpr bool all() const noexcept;  
Returns: count() == size().

constexpr bool any() const noexcept;  
Returns: count() != 0.

constexpr bool none() const noexcept;  
Returns: count() == 0.

22.9.3 bitset hash support
[bitset.hash]

template<size_t N> struct hash<bitset<N>>;

The specialization is enabled (22.10.19).

22.9.4 bitset operators
[bitset.operators]

template<size_t N>
constexpr bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) &= rhs.

template<size_t N>
constexpr bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) |= rhs.

template<size_t N>
constexpr bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) ^= rhs.

template<class charT, class traits, size_t N>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bitset<N>& x);

A formatted input function (31.7.5.3).

Effects: Extracts up to N characters from is. Stores these characters in a temporary object str of type basic_string<charT, traits>, then evaluates the expression x = bitset<N>(str). Characters are extracted and stored until any of the following occurs:

(5.1) N characters have been extracted and stored;
(5.2) end-of-file occurs on the input sequence;
(5.3) the next input character is neither is.widen('0') nor is.widen('1') (in which case the input character is not extracted).

If N > 0 and no characters are stored in str, ios_base::failbit is set in the input function’s local error state before setstate is called.

Returns: is.

template<class charT, class traits, size_t N>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);

Returns: os << x.template to_string<charT, traits, allocator<charT>>(
    use_facet<ctype<charT>>(os.getloc()).widen('0'),
    use_facet<ctype<charT>>(os.getloc()).widen('1'))
(see 31.7.6.3).
22.10 Function objects

22.10.1 General

A function object type is an object type (6.8.1) that can be the type of the postfix-expression in a function call (7.6.1.3, 12.2.2.2). A function object is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 27), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

22.10.2 Header `<functional>` synopsis

```cpp
namespace std {
  // 22.10.5, invoke
  template<class F, class... Args>
  constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args) noexcept(is_nothrow_invocable_v<F, Args...>);

  template<class R, class F, class... Args>
  constexpr R invoke_r(F&& f, Args&&... args) noexcept(is_nothrow_invocable_r_v<R, F, Args...>);

  // 22.10.6, reference_wrapper
  template<class T> class reference_wrapper;

  template<class T> constexpr reference_wrapper<T> ref(T&) noexcept;
  template<class T> constexpr reference_wrapper<const T> cref(const T&) noexcept;

  template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T>) noexcept;
  template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T>) noexcept;

1 [Example 1: If a C++ program wants to have a by-element addition of two vectors a and b containing double and put the result into a, it can do:

```
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```
—end example]

2 [Example 2: To negate every element of a:

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```
—end example]

22.10.3 Definitions [func.def]

1 The following definitions apply to this Clause:

2 A call signature is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

3 A callable type is a function object type (22.10) or a pointer to member.

4 A callable object is an object of a callable type.

5 A call wrapper type is a type that holds a callable object and supports a call operation that forwards to that object.

6 A call wrapper is an object of a call wrapper type.

7 A target object is the callable object held by a call wrapper.

8 A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the target object. These entities are collectively referred to as bound argument entities.

9 The target object and bound argument entities of the call wrapper are collectively referred to as state entities.

22.10.4 Requirements [func.require]

1 Define \textit{INVOKE}(f, t_1, t_2, \ldots, t_N) as follows:

\begin{itemize}
    \item \textit{INVOKE}(f, t_1, t_2, \ldots, t_N) when \( f \) is a pointer to a member function of a class \( T \) and \texttt{is\_same\_v<T, remove\_cvref\_t<decltype(t1)>> || is\_base\_of\_v<T, remove\_cvref\_t<decltype(t1)>>} is true;
    \item \texttt{(*t1).\*f}(t_2, \ldots, t_N) when \( f \) is a pointer to a member function of a class \( T \) and \texttt{reference\_wrapper} is a specialization of \texttt{reference\_wrapper};
    \item \texttt{(*t1).\*f}(t_2, \ldots, t_N) when \( f \) is a pointer to a member function of a class \( T \) and \( t_1 \) does not satisfy the previous two items;
    \item \texttt{t1.\*f} when \( N = 1 \) and \( f \) is a pointer to data member of a class \( T \) and \texttt{is\_same\_v<T, remove\_cvref\_t<decltype(t1)>> || is\_base\_of\_v<T, remove\_cvref\_t<decltype(t1)>>} is true;
    \item \texttt{(*t1).\*f} when \( N = 1 \) and \( f \) is a pointer to data member of a class \( T \) and \texttt{reference\_wrapper} is a specialization of \texttt{reference\_wrapper};
    \item \texttt{t1.\*f} when \( N = 1 \) and \( f \) is a pointer to data member of a class \( T \) and \( t_1 \) does not satisfy the previous two items;
    \item \texttt{f(t1, t_2, \ldots, t_N)} in all other cases.
\end{itemize}

2 Define \textit{INVOKE<\textit{R}}(f, t_1, t_2, \ldots, t_N) as \texttt{static\_cast<\textit{void}>(INVOKE(f, t_1, t_2, \ldots, t_N)) if \textit{R}} is \texttt{cv\textit{void}}, otherwise \textit{INVOKE}(f, t_1, t_2, \ldots, t_N) implicitly converted to \textit{R}. If \texttt{reference\_converts\_from\_temporary\_v<\textit{R}, decltype(INVOKE(f, t_1, t_2, \ldots, t_N)>>} is true, \textit{INVOKE<\textit{R}}(f, t_1, t_2, \ldots, t_N) is ill-formed.
Every call wrapper (22.10.3) meets the Cpp17MoveConstructible and Cpp17Destructible requirements. An argument forwarding call wrapper is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the target object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references.  

[Note 1: In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form]

```cpp
    template<class... UnBoundArgs>
    constexpr R operator()(UnBoundArgs&&... unbound_args) cv-qual;
```

— end note ]

A perfect forwarding call wrapper is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type `T` as `cv T&&` when the call is performed on an lvalue of the call wrapper type and as `cv T&` otherwise, where `cv` represents the cv-qualifiers of the call wrapper and where `cv` shall be neither volatile nor const volatile.

A call pattern defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (3.20) to an expression `e` determined from its call pattern `cp` by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

A simple call wrapper is a perfect forwarding call wrapper that meets the Cpp17CopyConstructible and Cpp17CopyAssignable requirements and whose copy constructor, move constructor, and assignment operators are constexpr functions that do not throw exceptions.

The copy/move constructor of an argument forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.4.5.3).

[Note 2: This implies that each of the copy/move constructors has the same exception-specification as the corresponding implicit definition and is declared as constexpr if the corresponding implicit definition would be considered to be constexpr. — end note]

Argument forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

### 22.10.5 invoke functions

```cpp
template<class F, class... Args>
constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args) noexcept(is_nothrow_invocable_v<F, Args...>);
```

1 Constraints: `is_invocable_v<F, Args...>` is true.

2 Returns: `INVOKE(std::forward<F>(f), std::forward<Args>(args)...)` (22.10.4).

```cpp
template<class R, class F, class... Args>
constexpr R invoke_r(F&& f, Args&&... args) noexcept(is_nothrow_invocable_r_v<R, F, Args...>);
```

3 Constraints: `is_invocable_r_v<R, F, Args...>` is true.

4 Returns: `INVOKE<R>(std::forward<F>(f), std::forward<Args>(args)...)` (22.10.4).

### 22.10.6 Class template reference_wrapper

#### 22.10.6.1 General

```cpp
namespace std {
    template<class T> class reference_wrapper {
        public:
            // types
            using type = T;

            // 22.10.6.2, constructors
            template<class U>
            constexpr reference_wrapper(U&&) noexcept(see below);
            constexpr reference_wrapper(const reference_wrapper& x) noexcept;

            // 22.10.6.3, assignment
            constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;
    }
}
```

§ 22.10.6.1
// 22.10.6.4, access
constexpr operator T& () const noexcept;
constexpr T& get() const noexcept;

// 22.10.6.5, invocation
template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const	noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);

};

template<class T>
reference_wrapper(T&) -> reference_wrapper<T>;

1 reference_wrapper<T> is a Cpp17CopyConstructible and Cpp17CopyAssignable wrapper around a reference to an object or function of type T.

2 reference_wrapper<T> is a trivially copyable type (6.8.1).

3 The template parameter T of reference_wrapper may be an incomplete type.

22.10.6.2 Constructors

template<class U>
constexpr reference_wrapper(U&& u) noexcept(
    see below);

1 Let FUN denote the exposition-only functions
   void FUN(T&) noexcept;
   void FUN(T&&) = delete;

2 Constraints: The expression FUN(declval<U>()) is well-formed and is_same_v<remove_cvref_t<U>,
   reference_wrapper> is false.

3 Effects: Creates a variable r as if by T& r = std::forward<U>(u), then constructs a reference_-
   wrapper object that stores a reference to r.

4 Remarks: The exception specification is equivalent to noexcept(FUN(declval<U>())).

constexpr reference_wrapper(const reference_wrapper& x) noexcept;

5 Effects: Constructs a reference_wrapper object that stores a reference to x.get().

22.10.6.3 Assignment

constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

1 Postconditions: *this stores a reference to x.get().

22.10.6.4 Access

constexpr operator T& () const noexcept;

1 Returns: The stored reference.

constexpr T& get() const noexcept;

2 Returns: The stored reference.

22.10.6.5 Invocation

template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&... args) const
    noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);

1 Mandates: T is a complete type.

2 Returns: INVOKE(get(), std::forward<ArgTypes>(args)...). (22.10.4)

22.10.6.6 Helper functions

1 The template parameter T of the following ref and cref function templates may be an incomplete type.
template<class T> constexpr reference_wrapper<T> ref(T& t) noexcept;

Returns: reference_wrapper<T>(t).

template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;

Returns: t.

template<class T> constexpr reference_wrapper<const T> cref(const T& t) noexcept;

Returns: reference_wrapper<const T>(t).

template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;

Returns: t.

22.10.6.7 common_reference related specializations

namespace std {
    template<class T>
    constexpr bool is-ref-wrapper = false;
    // exposition only

template<class T>
    constexpr bool is-ref-wrapper<reference_wrapper<T>> = true;

template<class R, class T, class RQ, class TQ>
    concept ref-wrap-common-reference-exists-with =
        // exposition only
        is-ref-wrapper<R> &&
        requires { typename common_reference_t<typename R::type&, TQ>; } &&
        convertible_to<RQ, common_reference_t<typename R::type&, TQ>>;

template<class R, class T, template<class> class RQual, template<class> class TQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
        !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>) struct basic_common_reference<R, T, RQual, TQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };

template<class T, class R, template<class> class TQual, template<class> class RQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
        !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>) struct basic_common_reference<T, R, TQual, RQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };
}

22.10.7 Arithmetic operations

22.10.7.1 General

The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).

22.10.7.2 Class template plus

template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x + y.

template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));

    using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) + std::forward<U>(u));

Returns: std::forward<T>(t) + std::forward<U>(u).

22.10.7.3 Class template minus

template<class T = void> struct minus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x - y.

template<> struct minus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) - std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) - std::forward<U>(u));

2 Returns: std::forward<T>(t) - std::forward<U>(u).

22.10.7.4 Class template multiplies

template<class T = void> struct multiplies {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x * y.

template<> struct multiplies<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) * std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) * std::forward<U>(u));

2 Returns: std::forward<T>(t) * std::forward<U>(u).

22.10.7.5 Class template divides

template<class T = void> struct divides {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x / y.

template<> struct divides<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) / std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) / std::forward<U>(u));

2 Returns: std::forward<T>(t) / std::forward<U>(u).
22.10.7.6 Class template modulus

```cpp
template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: \( x \% y \).

```cpp
template<> struct modulus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) % std::forward<U>(u));
}
```

2 Returns: \( \text{std::forward<T>(t) \% std::forward<U>(u)} \).

22.10.7.7 Class template negate

```cpp
template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};
```

1 Returns: \( -x \).

```cpp
template<> struct negate<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));
}
```

2 Returns: \( -\text{std::forward<T>(t)} \).

22.10.8 Comparisons

22.10.8.1 General

The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

2 For templates \texttt{less}, \texttt{greater}, \texttt{less\_equal}, and \texttt{greater\_equal}, the specializations for any pointer type yield a result consistent with the implementation-defined strict total order over pointers (3.26).

\[ \text{Note 1: If } a < b \text{ is well-defined for pointers } a \text{ and } b \text{ of type } P, \text{ then } (a < b) \iff \text{less}\_P()\(a, b) \iff \text{greater}\_P()\(a, b), \text{ and so forth.} \text{—end note} \]

For template specializations \texttt{less\_void}, \texttt{greater\_void}, \texttt{less\_equal\_void}, and \texttt{greater\_equal\_void}, if the call operator calls a built-in operator comparing pointers, the call operator yields a result consistent with the implementation-defined strict total order over pointers.

22.10.8.2 Class template equal\_to

```cpp
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

1 Returns: \( x == y \).
template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));

2 Returns: std::forward<T>(t) == std::forward<U>(u).

22.10.8.3 Class template not_equal_to

template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

cconstexpr bool operator()(const T& x, const T& y) const;

1 Returns: x != y.

template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) != std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));

2 Returns: std::forward<T>(t) != std::forward<U>(u).

22.10.8.4 Class template greater

template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};

cconstexpr bool operator()(const T& x, const T& y) const;

1 Returns: x > y.

template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) > std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));

2 Returns: std::forward<T>(t) > std::forward<U>(u).

22.10.8.5 Class template less

template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};

cconstexpr bool operator()(const T& x, const T& y) const;

1 Returns: x < y.

template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) < std::forward<U>(u));

§ 22.10.8.5 784
using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) < std::forward<U>(u));

Returns: std::forward<T>(t) < std::forward<U>(u).

22.10.8.6 Class template greater_equal

[comparisons.greater.equal]

template<class T = void> struct greater_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

customexpr bool operator()(const T& x, const T& y) const;

Returns: x >= y.

template<> struct greater_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) >= std::forward<U>(u));

Returns: std::forward<T>(t) >= std::forward<U>(u).

22.10.8.7 Class template less_equal

[comparisons.less.equal]

template<class T = void> struct less_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

customexpr bool operator()(const T& x, const T& y) const;

Returns: x <= y.

template<> struct less_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) <= std::forward<U>(u));

Returns: std::forward<T>(t) <= std::forward<U>(u).

22.10.8.8 Class compare_three_way

[comparisons.three.way]

namespace std {
  struct compare_three_way {
    template<class T, class U>
      constexpr auto operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
  };
}

template<class T, class U>
  constexpr auto operator()(T&& t, U&& u) const;

Constraints: T and U satisfy three_way_comparable_with.

Preconditions: If the expression std::forward<T>(t) <=> std::forward<U>(u) results in a call to a built-in operator <=> comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model three_way_comparable_with.
Effects:

(3.1) If the expression \( \text{std::forward}<T>(t) \ <=> \text{std::forward}<U>(u) \) results in a call to a built-in operator \( \Rightarrow \) comparing pointers of type \( P \), returns \text{strong_ordering::less} \) if (the converted value of) \( t \) precedes \( u \) in the implementation-defined strict total order over pointers (3.26), \text{strong_ordering::greater} \) if \( u \) precedes \( t \), and otherwise \text{strong_ordering::equal} \)

(3.2) Otherwise, equivalent to: return \( \text{std::forward}<T>(t) \ <=> \text{std::forward}<U>(u) \);

22.10.9 Concept-constrained comparisons

struct ranges::equal_to {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const {
    using is_transparent = unspecified;
  }
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: \( T \) and \( U \) satisfy \text{equality_comparable_with}.

Preconditions: If the expression \( \text{std::forward}<T>(t) \ \Rightarrow \text{std::forward}<U>(u) \) results in a call to a built-in operator \( \Rightarrow \) comparing pointers, the conversion sequences from both \( T \) and \( U \) to \( P \) are equality-preserving (18.2); otherwise, \( T \) and \( U \) model \text{equality_comparable_with}.

Effects:

(3.1) If the expression \( \text{std::forward}<T>(t) \ \Rightarrow \text{std::forward}<U>(u) \) results in a call to a built-in operator \( \Rightarrow \) comparing pointers: returns \text{false} \) if either (the converted value of) \( t \) precedes \( u \) or \( u \) precedes \( t \) in the implementation-defined strict total order over pointers (3.26) and otherwise \text{true}.

(3.2) Otherwise, equivalent to: return \( \text{std::forward}<T>(t) \ \Rightarrow \text{std::forward}<U>(u) \);

struct ranges::not_equal_to {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const {
    using is_transparent = unspecified;
  }
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: \( T \) and \( U \) satisfy \text{equality_comparable_with}.

Effects: Equivalent to:

\( \text{return } \!\!\text{ranges::equal_to}()<\text{std::forward}<T>(t), \text{std::forward}<U>(u)>; \)

struct ranges::greater {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const {
    using is_transparent = unspecified;
  }
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: \( T \) and \( U \) satisfy \text{totally_ordered_with}.

Effects: Equivalent to:

\( \text{return ranges::less}()<\text{std::forward}<U>(u), \text{std::forward}<T>(t)>; \)

struct ranges::less {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;
};
using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Preconditions: If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a
built-in operator < comparing pointers of type P, the conversion sequences from both T and U to P are
equality-preserving (18.2); otherwise, T and U model totally_ordered_with. For any expressions ET
and EU such that decltype((ET)) is T and decltype((EU)) is U, exactly one of ranges::less{}(ET, EU),
ranges::less{}(EU, ET), or ranges::equal_to{}(ET, EU) is true.

Effects:
— If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in
operator < comparing pointers: returns true if (the converted value of) t precedes u in the
implementation-defined strict total order over pointers (3.26) and otherwise false.

— Otherwise, equivalent to: return std::forward<T>(t) < std::forward<U>(u);

struct ranges::greater_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Effects: Equivalent to:
return !ranges::less{}(std::forward<T>(t), std::forward<U>(u));

struct ranges::less_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Effects: Equivalent to:
return !ranges::less{}(std::forward<U>(u), std::forward<T>(t));

22.10 Logical operations

22.10.1 General

The library provides basic function object classes for all of the logical operators in the language (7.6.14,
7.6.15, 7.6.2.2).

22.10.2 Class template logical_and

template<class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x && y.
template<> struct logical_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) && std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

22.10.10.3 Class template logical_or

template<class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

1 Returns: x || y.

template<> struct logical_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));

2 Returns: std::forward<T>(t) || std::forward<U>(u).

22.10.10.4 Class template logical_not

template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;

1 Returns: !x.

template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));

    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));

2 Returns: !std::forward<T>(t).

22.10.11 Bitwise operations

22.10.11.1 General

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.2).

22.10.11.2 Class template bit_and

template<class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};
constexpr T operator()(const T& x, const T& y) const;

Returns: \( x \& y \).

template<> struct bit_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) \& std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) \& std::forward<U>(u));

Returns: \( \text{std::forward<T>(t)} \& \text{std::forward<U>(u)} \).

### 22.10.11.3 Class template bit_or

template<class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: \( x | y \).

template<> struct bit_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) | std::forward<U>(u));

Returns: \( \text{std::forward<T>(t)} | \text{std::forward<U>(u)} \).

### 22.10.11.4 Class template bit_xor

template<class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: \( x ^ y \).

template<> struct bit_xor<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) ^ std::forward<U>(u));

Returns: \( \text{std::forward<T>(t)} ^ \text{std::forward<U>(u)} \).

### 22.10.11.5 Class template bit_not

template<class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};

castexpr T operator()(const T& x) const;

Returns: \( \sim x \).
template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
         -> decltype(~std::forward<T>(t));
    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
         -> decltype(~std::forward<T>(t));

22.10.12 Class identity

struct identity {
    template<class T>
        constexpr T&& operator()(T&& t) const noexcept;
    using is_transparent = unspecified;
};

template<class T>
    constexpr T&& operator()(T&& t) const noexcept;

1 Effects: Equivalent to: return std::forward<T>(t);

22.10.13 Function template not_fn

template<class F> constexpr unspecified not_fn(F&& f);

1 In the text that follows:
(1.1) — g is a value of the result of a not_fn invocation,
(1.2) — FD is the type decay_t<F>,
(1.3) — fd is the target object of g (22.10.3) of type FD, direct-non-list-initialized with std::forward<F>(f),
(1.4) — call_args is an argument pack used in a function call expression (7.6.1.3) of g.

2 Mandates: is_constructible_v<FD, F> && is_move_constructible_v<FD> is true.

3 Preconditions: FD meets the Cpp17MoveConstructible requirements.

4 Returns: A perfect forwarding call wrapper (22.10.4) g with call pattern !invoke(fd, call_args...).

5 Throws: Any exception thrown by the initialization of fd.

template<auto f> constexpr unspecified not_fn() noexcept;

6 In the text that follows:
(6.1) — F is the type of f,
(6.2) — g is a value of the result of a not_fn invocation,
(6.3) — call_args is an argument pack used in a function call expression (7.6.1.3) of g.

7 Mandates: If is_pointer_v<F> || is_member_pointer_v<F> is true, then f != nullptr is true.

8 Returns: A perfect forwarding call wrapper (22.10.4) g that does not have state entities, and has the call pattern !invoke(f, call_args...).

22.10.14 Function templates bind_front and bind_back

template<class F, class... Args>
    constexpr unspecified bind_front(F&& f, Args&&... args);

template<class F, class... Args>
    constexpr unspecified bind_back(F&& f, Args&&... args);

1 Within this subclause:
(1.1) — g is a value of the result of a bind_front or bind_back invocation,
(1.2) FD is the type decay_t<F>.
(1.3) fd is the target object of g (22.10.3) of type FD, direct-non-list-initialized with std::forward<F>(f),
(1.4) BoundArgs is a pack that denotes decay_t<Args>..., 
(1.5) bound_args is a pack of bound argument entities of g (22.10.3) of types BoundArgs..., direct-
non-list-initialized with std::forward<Args>(args)..., respectively, and
(1.6) call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates:

\[
\text{is_constructible_v<FD, F> } \&\&
\text{is_move_constructible_v<FD> } \&\&
\text{is_constructible_v<BoundArgs, Args> } \&\& \ldots \&\&
\text{is_move_constructible_v<BoundArgs> } \&\& \ldots
\]

is true.

Preconditions: FD meets the Cpp17MoveConstructible requirements. For each Ti in BoundArgs, if Ti is 
an object type, Ti meets the Cpp17MoveConstructible requirements.

Returns: A perfect forwarding call wrapper (22.10.4) g with call pattern:

(4.1) invoke(fd, bound_args..., call_args...) for a bind_front invocation, or
(4.2) invoke(fd, call_args..., bound_args...) for a bind_back invocation.

Throws: Any exception thrown by the initialization of the state entities of g (22.10.3).

```
template<auto f, class... Args>
constexpr unspecified bind_front(Args&&... args);
template<auto f, class... Args>
constexpr unspecified bind_back(Args&&... args);
```

Within this subclause:

(6.1) F is the type of f,
(6.2) g is a value of the result of a bind_front or bind_back invocation,
(6.3) BoundArgs is a pack that denotes decay_t<Args>..., 
(6.4) bound_args is a pack of bound argument entities of g (22.10.3) of types BoundArgs..., direct-
non-list-initialized with std::forward<Args>(args)..., respectively, and
(6.5) call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates:

(7.1) (is_constructible_v<BoundArgs, Args> && ...) is true, and
(7.2) (is_move_constructible_v<BoundArgs> && ...) is true, and
(7.3) if is_pointer_v<F> || is_member_pointer_v<F> is true, then f != nullptr is true.

Preconditions: For each Ti in BoundArgs, Ti meets the Cpp17MoveConstructible requirements.

Returns: A perfect forwarding call wrapper (22.10.4) g that does not have a target object, and has the 
call pattern:

(9.1) invoke(f, bound_args..., call_args...) for a bind_front invocation, or
(9.2) invoke(f, call_args..., bound_args...) for a bind_back invocation.

Throws: Any exception thrown by the initialization of bound_args.

22.10.15 Function object binders

22.10.15.1 General

Subclause 22.10.15 describes a uniform mechanism for binding arguments of callable objects.

22.10.15.2 Class template is_bind_expression

```
namespace std {
    template<class T> struct is_bind_expression; // see below
}
```

§ 22.10.15.2 791
The class template is_bind_expression can be used to detect function objects generated by bind. The function template bind uses is_bind_expression to detect subexpressions.

Specializations of the is_bind_expression template shall meet the Cpp17UnaryTypeTrait requirements (21.3.2). The implementation provides a definition that has a base characteristic of true_type if T is a type returned from bind, otherwise it has a base characteristic of false_type. A program may specialize this template for a program-defined type T to have a base characteristic of true_type to indicate that T should be treated as a subexpression in a bind call.

22.10.15.3 Class template is_placeholder

namespace std {
  template<class T> struct is_placeholder; // see below
}

1 The class template is_placeholder can be used to detect the standard placeholders _1, _2, and so on (22.10.15.5). The function template bind uses is_placeholder to detect placeholders.

2 Specializations of the is_placeholder template shall meet the Cpp17UnaryTypeTrait requirements (21.3.2). The implementation provides a definition that has the base characteristic of integral_constant<int, J> if T is the type of std::placeholders::J, otherwise it has a base characteristic of integral_constant<int, 0>. A program may specialize this template for a program-defined type T to have a base characteristic of integral_constant<int, N> with N > 0 to indicate that T should be treated as a placeholder type.

22.10.15.4 Function template bind

template<class F, class... BoundArgs>
constexpr unspecified bind(F& f, BoundArgs&&... bound_args);

Mandates: is_constructible_v<FD, F> is true. For each Ti in BoundArgs, is_constructible_v<
  TDi, Ti> is true.

Preconditions: FD and each TDi meet the Cpp17MoveConstructible and Cpp17Destructible requirements. INVOKE(fd, w1, w2, ..., wN) (22.10.4) is a valid expression for some values w1, w2, ..., wN, where N has the value sizeof...(bound_args).

Returns: An argument forwarding call wrapper g (22.10.4). A program that attempts to invoke a volatile-qualified g is ill-formed. When g is not volatile-qualified, invocation of g(u1, u2, ..., uM) is expression-equivalent (3.20) to

INVOKE(static_cast<Vi>(u1)),
  static_cast<Vi>(u1), static_cast<V2>(u2), ..., static_cast<VN>(uN))

for the first overload, and

INVOKE<R>(static_cast<Vi>(u1)),
  static_cast<Vi>(u1), static_cast<V2>(u2), ..., static_cast<VN>(uN))

§ 22.10.15.4
for the second overload, where the values and types of the target argument \( v_{fd} \) and of the bound arguments \( v_1, v_2, \ldots, v_N \) are determined as specified below.

Throws: Any exception thrown by the initialization of the state entities of \( g \).

[Note 1: If all of \( FD \) and \( TD_i \) meet the requirements of \texttt{Cpp17CopyConstructible}, then the return type meets the requirements of \texttt{Cpp17CopyConstructible}. — end note]

The values of the bound arguments \( v_1, v_2, \ldots, v_N \) and their corresponding types \( V_1, V_2, \ldots, V_N \) depend on the types \( TD_i \) derived from the call to \texttt{bind} and the cv-qualifiers \( cv \) of the call wrapper \( g \) as follows:

- (7.1) if \( TD_i \) is \texttt{reference_wrapper<T>}, the argument is \( td_i().get() \) and its type \( V_i \) is \( T& \);
- (7.2) if the value of \texttt{is_bind_expression_v<TD_i>} is true, the argument is \( \text{static_cast<cv TD_i&>(td_i)}(\text{std::forward<U_j>(u_j)}...) \) and its type \( V_i \) is \( \text{invoke_result_t<cv TD_i&, U_j...>&&} \);
- (7.3) if the value \( j \) of \texttt{is_placeholder_v<TD_i>} is not zero, the argument is \( \text{std::forward<U_j>(u_j)} \) and its type \( V_i \) is \( U_j&& \);
- (7.4) otherwise, the value is \( td_i \) and its type \( V_i \) is \( cv TD_i& \).

The value of the target argument \( v_{fd} \) is \( fd \) and its corresponding type \( V_{fd} \) is \( cv FD& \).

22.10.15.5 Placeholders

```cpp
namespace std::placeholders {
  // M is the number of placeholders
  see below _1;
  see below _2;
  .
  .
  see below _M;
}
```

1 The number \( M \) of placeholders is implementation-defined.

2 All placeholder types meet the \texttt{Cpp17DefaultConstructible} and \texttt{Cpp17CopyConstructible} requirements, and their default constructors and copy/move constructors are constexpr functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the \texttt{Cpp17CopyAssignable} requirements, but if so, their copy assignment operators are constexpr functions that do not throw exceptions.

3 Placeholders should be defined as:

```cpp
inline constexpr unspecified _1{};
```

If they are not, they are declared as:

```cpp
extern unspecified _1;
```

4 Placeholders are freestanding items (16.3.3.6).

22.10.16 Function template \texttt{mem_fn}

```cpp
template<class R, class T> constexpr unspecified mem_fn(R T::* pm) noexcept;
```

1 Returns: A simple call wrapper (22.10.4) \( fn \) with call pattern \( \text{invoke(pm, call_args...)} \), where \( pm \) is the target object of \( fn \) of type \( R T::* \) direct-non-list-initialized with \( pm \), and \( call_args \) is an argument pack used in a function call expression (7.6.1.3) of \( fn \).

22.10.17 Polymorphic function wrappers

22.10.17.1 General

Subclause 22.10.17 describes polymorphic wrapper classes that encapsulate arbitrary callable objects.

Let \( t \) be an object of a type that is a specialization of \texttt{function}, \texttt{copyable_function}, or \texttt{move_only_function}, such that the target object \( x \) of \( t \) has a type that is a specialization of \texttt{function}, \texttt{copyable_function}, or \texttt{move_only_function}. Each argument of the invocation of \( x \) evaluated as part of the invocation of \( t \) may alias an argument in the same position in the invocation of \( t \) that has the same type, even if the corresponding parameter is not of reference type.

[Example 1:}
move_only_function<void(T)>
    f{copyable_function<void(T)>::[]() {}};
T t;
f(t);    // it is unspecified how many copies of T are made

Recommended practice: Implementations should avoid double wrapping when constructing polymorphic wrappers from one another.

22.10.17.2 Class bad_function_call

An exception of type bad_function_call is thrown by function::operator() (22.10.17.3.5) when the function wrapper object has no target.

namespace std {
    class bad_function_call : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

22.10.17.3 Class template function

22.10.17.3.1 General

namespace std {
    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;
            // 22.10.17.3.2, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&) noexcept;
            template<class F> function(F&&);
            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(reference_wrapper<F>) noexcept;
            ~function();
            // 22.10.17.3.3, function modifiers
            void swap(function&) noexcept;
            // 22.10.17.3.4, function capacity
            explicit operator bool() const noexcept;
            // 22.10.17.3.5, function invocation
            R operator()(ArgTypes...) const;
            // 22.10.17.3.6, function target access
            const type_info& target_type() const noexcept;
            template<class T> T* target() const noexcept;
            template<class T> const T* target() const noexcept;
    };

§ 22.10.17.3.1
The function class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (22.10.3), given a call signature (22.10.3).

A callable type (22.10.3) F is Lvalue-Callable for argument types ArgTypes and return type R if the expression `INVOKER<R>(declval<F&>(), declval<ArgTypes>()...)`, considered as an unevaluated operand (7.2.3), is well-formed (22.10.4).

The function class template is a call wrapper (22.10.3) whose call signature (22.10.3) is `R(ArgTypes...)`.

[Note 1: The types deduced by the deduction guides for function might change in future revisions of C++. — end note]

22.10.17.3.2 Constructors and destructor

function() noexcept;

Postconditions: !*this.

function(nullptr_t) noexcept;

Postconditions: !*this.

function(const function& f);

Postconditions: !*this if !f; otherwise, the target object of *this is a copy of f.target().

Thros: Nothing if f's target is a specialization of reference_wrapper or a function pointer. Otherwise, may throw bad_alloc or any exception thrown by the copy constructor of the stored callable object.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f's target is an object holding only a pointer or reference to an object and a member function pointer.

function(function&& f) noexcept;

Postconditions: If !f, *this has no target; otherwise, the target of *this is equivalent to the target of f before the construction, and f is in a valid state with an unspecified value.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f's target is an object holding only a pointer or reference to an object and a member function pointer.

template<class F> function(F&& f);

Let FD be decay_t<F>.

Constraints:

- is_same_v<remove_cvref_t<F>, function> is false, and
- FD is Lvalue-Callable (22.10.17.3) for argument types ArgTypes... and return type R.

Mandates:

- is_copy_constructible_v<FD> is true, and
- is_constructible_v<FD, F> is true.

Preconditions: FD meets the Cpp17CopyConstructible requirements.

Postconditions: !*this is true if any of the following hold:

- f is a null function pointer value.
- f is a null member pointer value.
- remove_cvref_t<F> is a specialization of the function class template, and !f is true.

Otherwise, *this has a target object of type FD direct-non-list-initialized with std::forward<F>(f).
14 **Throws:** Nothing if FD is a specialization of `reference_wrapper` or a function pointer type. Otherwise, may throw `bad_alloc` or any exception thrown by the initialization of the target object.

15 **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f refers to an object holding only a pointer or reference to an object and a member function pointer.

```cpp
template<class F> function(F) -> function<see below>;
```

16 **Constraints:** 
- F::operator() is non-static member function and `decltype(&F::operator())` is of the form `R(G::*)(A...) cv k_opt noexcept opt` or of the form `R(*)(G, A...) noexcept opt` for a type G, or
- F::operator() is static member function and `decltype(&F::operator())` is of the form `R(*)(A...) noexcept opt`.

17 **Remarks:** The deduced type is `function<R(A...)`.

```cpp
function& operator=(const function& f);
```

18 **Effects:** As if by `function(f).swap(*this);`

19 **Returns:** *this.

```cpp
function& operator=(function&& f);
```

20 **Effects:** Replaces the target of *this with the target of f.

21 **Returns:** *this.

```cpp
function& operator=(nullptr_t) noexcept;
```

22 **Effects:** If *this != nullptr, destroys the target of this.

23 **Postconditions:** !(*this).

24 **Returns:** *this.

```cpp
template<class F> function& operator=(F&& f);
```

25 **Constraints:** `decay_t<F>` is Lvalue-Callable (22.10.17.3) for argument types `ArgTypes`... and return type R.

26 **Effects:** As if by: `function(std::forward<F>(f)).swap(*this);`

27 **Returns:** *this.

```cpp
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

28 **Effects:** As if by: `function(f).swap(*this);`

29 **Returns:** *this.

30 **~function();**

31 **Effects:** If *this != nullptr, destroys the target of this.

22.10.17.3.3 **Modifiers**

`void swap(function& other) noexcept;` 

**Effects:** Interchanges the target objects of *this and other.

22.10.17.3.4 **Capacity**
explicit operator bool() const noexcept;

1 Returns: true if *this has a target, otherwise false.

22.10.17.3.5 Invocation

R operator()(ArgTypes... args) const;

1 Returns: INVOKE\(<\text{\textbackslash f}, \text{std::forward<ArgTypes>(args)}...\rangle\) (22.10.4), where f is the target object (22.10.3) of *this.

2 Throws: bad_function_call if !*this; otherwise, any exception thrown by the target object.

22.10.17.3.6 Target access

cost type_info& target_type() const noexcept;

1 Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;

2 Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

22.10.17.3.7 Null pointer comparison operator functions

template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;

1 Returns: !f.

22.10.17.3.8 Specialized algorithms

template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;

1 Effects: As if by: f1.swap(f2);

22.10.17.4 Move-only wrapper

22.10.17.4.1 General

The header provides partial specializations of move_only_function for each combination of the possible replacements of the placeholders cv, ref, and noex where

(1.1) — cv is either const or empty,

(1.2) — ref is either & or &&, or empty, and

(1.3) — noex is either true or false.

2 For each of the possible combinations of the placeholders mentioned above, there is a placeholder inv-quals defined as follows:

(2.1) — If ref is empty, let inv-quals be cv&,

(2.2) — otherwise, let inv-quals be cv ref.

22.10.17.4.2 Class template move_only_function

namespace std {

template<class R, class... ArgTypes>
class move_only_function<R(ArgTypes...) cv ref noexcept(noex)> {

  using result_type = R;

// 22.10.17.4.3, constructors, assignment, and destructor
  move_only_function() noexcept;
  move_only_function(nullptr_t) noexcept;
  move_only_function(move_only_function&&) noexcept;
  template<class F> move_only_function(F&&);
  template<class T, class... Args>
    explicit move_only_function(in_place_type_t<T>, Args&&...);

§ 22.10.17.4.2 797
The `move_only_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, move, and call arbitrary callable objects, given a call signature.

**Recommended practice**: Implementations should avoid the use of dynamically allocated memory for a small contained value.

[Note 1: Such small-object optimization can only be applied to a type `T` for which `is_nothrow_move_constructible_v<T>` is true. — end note]

### 22.10.17.4.3 Constructors, assignment, and destructor

```cpp
template<class VT>
static constexpr bool is-callable-from = see below; // exposition only
};
```

1. If `noex` is true, `is-callable-from<VT>` is equal to:
   ```cpp
   is_nothrow_invocable_r_v<R, VT cv ref, ArgTypes...> &&
   is_nothrow_invocable_r_v<R, VT inv-quals, ArgTypes...>
   ```
2. Otherwise, `is-callable-from<VT>` is equal to:
   ```cpp
   is_invocable_r_v<R, VT cv ref, ArgTypes...> &&
   is_invocable_r_v<R, VT inv-quals, ArgTypes...>
   ```

```cpp
move_only_function() noexcept;
move_only_function(nullptr_t) noexcept;
```

2. **Postconditions**: `*this` has no target object.

```cpp
move_only_function(move_only_function&& f) noexcept;
```

3. **Postconditions**: The target object of `*this` is the target object `f` had before construction, and `f` is in a valid state with an unspecified value.

```cpp
template<class F> move_only_function(F&& f);
```

4. Let `VT` be `decay_t<F>.

5. **Constraints**:
   - (5.1) `remove_cvref_t<F>` is not the same type as `move_only_function`, and
   - (5.2) `remove_cvref_t<F>` is not a specialization of `in_place_type_t`, and
   - (5.3) `is-callable-from<VT>` is true.
Mandates: is_constructible_v<VT, F> is true.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT>

Postconditions: *this has no target object if any of the following hold:
is true, VT meets the Cpp17MoveConstructible requirements.

Preconditions: *this has no target object if any of the following hold:

Postconditions: *this has a target object of type VT direct-non-list-initialized with std::forward<F>(f).

Constraints:

Constraints:

Mandates: VT is the same type as T.

Constraints:

Mandates: VT is the same type as T.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT>

Postconditions: *this has a target object of type VT direct-non-list-initialized with std::forward<Args>

Throws: Any exception thrown by the initialization of the target object. May throw bad_alloc unless

Mandates: VT is the same type as T.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT>

Postconditions: *this has a target object of type VT direct-non-list-initialized with std::forward<Args>

Throws: Any exception thrown by the initialization of the target object. May throw bad_alloc unless

Effects: Equivalent to: move_only_function(std::move(f)).swap(*this);

Returns: *this.

Effects: Equivalent to: move_only_function(std::forward<F>(f)).swap(*this);
Returns: *this.

~move_only_function();

Effects: Destroys the target object of *this, if any.

### 22.10.17.4.4 Invocation

```cpp
explicit operator bool() const noexcept;
```

Returns: true if *this has a target object, otherwise false.

```cpp
R operator()(ArgTypes... args) cv ref noexcept(noex);
```

Preconditions: *this has a target object.

Effects: Equivalent to:

```
return INVOKE<R>(static_cast<F<inv-quals>(f), std::forward<ArgTypes>(args)...);
```

where f is an lvalue designating the target object of *this and F is the type of f.

### 22.10.17.4.5 Utility

```cpp
void swap(move_only_function& other) noexcept;
```

Effects: Exchanges the target objects of *this and other.

```cpp
friend void swap(move_only_function& f1, move_only_function& f2) noexcept;
```

Effects: Equivalent to f1.swap(f2).

```cpp
friend bool operator==(const move_only_function& f, nullptr_t) noexcept;
```

Returns: true if f has no target object, otherwise false.

### 22.10.17.5 Copyable wrapper

#### 22.10.17.5.1 General

The header provides partial specializations of copyable_function for each combination of the possible replacements of the placeholders cv, ref, and noex where

- (1.1) cv is either const or empty,
- (1.2) ref is either &, &&, or empty, and
- (1.3) noex is either true or false.

For each of the possible combinations of the placeholders mentioned above, there is a placeholder inv-quals defined as follows:

- (2.1) If ref is empty, let inv-quals be cv&,
- (2.2) otherwise, let inv-quals be cv ref.

#### 22.10.17.5.2 Class template copyable_function

```cpp
namespace std {
    template<class R, class... ArgTypes>
    class copyable_function<R(ArgTypes...) cv ref noexcept(noex)> {
        public:
            using result_type = R;

            // 22.10.17.5.3, constructors, assignments, and destructors
            copyable_function() noexcept;
            copyable_function(nullptr_t) noexcept;
            copyable_function(const copyable_function&);
            copyable_function(copyable_function&&) noexcept;
            template<class F> copyable_function(F&&);
            template<class T, class... Args>
                explicit copyable_function(in_place_type_t<T>, Args&&...);
            template<class T, class U, class... Args>
                explicit copyable_function(in_place_type_t<T>, initializer_list<U>, Args&&...);
```
The `copyable_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, copy, move, and call arbitrary callable objects, given a call signature.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for a small contained value.

[Note 1: Such small-object optimization can only be applied to a type \( T \) for which `is_nothrow_move_constructible_v<T>` is true. — end note]

### 22.10.17.5.3 Constructors, assignments, and destructors

1. The `copyable_function` class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, copy, move, and call arbitrary callable objects, given a call signature.

2. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

3. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

4. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

5. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

6. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

7. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

7. **Recommended practice:** Implementations should avoid the use of dynamically allocated memory for a small contained value.

---

copyable_function() noexcept;
copyable_function(nullptr_t) noexcept;

copyable_function(const copyable_function& f);

Postconditions: *this has no target object.

Postconditions: *this has no target object if \( f \) had no target object. Otherwise, the target object of *this is a copy of the target object of \( f \).

Throw: Any exception thrown by the initialization of the target object. May throw `bad_alloc`.

Postconditions: The target object of *this is the target object \( f \) had before construction, and \( f \) is in a valid state with an unspecified value.

template<class F> copyable_function(F&& f);

Let \( VT \) be `decay_t<F>`.

Constraints:

1. `remove_cvref_t<F>` is not the same type as `copyable_function`, and
2. `remove_cvref_t<F>` is not a specialization of `in_place_type_t`, and

§ 22.10.17.5.3 801
(7.3) \( \text{is-callable-from}<\text{VT} \) is true.

*Mandates:*

(8.1) \( \text{is_constructible_v}<\text{VT}, \text{F} \) is true, and

(8.2) \( \text{is_copy_constructible_v}<\text{VT} \) is true.

*Preconditions:* \( \text{VT} \) meets the \text{Cpp17Destructible} and \text{Cpp17CopyConstructible} requirements.

*Postconditions:* \( \star\text{this} \) has no target object if any of the following hold:

(10.1) \( f \) is a null function pointer value, or

(10.2) \( f \) is a null member pointer value, or

(10.3) \( \text{remove_cvref_t}<\text{F} \) is a specialization of the \text{copyable_function} class template, and \( f \) has no target object.

Otherwise, \( \star\text{this} \) has a target object of type \( \text{VT} \) direct-non-list-initialized with \( \text{std::forward<}\text{F}>(f) \).

*Throws:* Any exception thrown by the initialization of the target object. May throw \text{bad_alloc} unless \( \text{VT} \) is a function pointer or a specialization of \text{reference_wrapper}.

```cpp
template<class T, class... Args>
explicit copyable_function(in_place_type_t<T>, Args&&... args);
```

Let \( \text{VT} \) be \( \text{decay_t}<\text{T} \).

*Constraints:*

(13.1) \( \text{is_constructible_v}<\text{VT}, \text{Args}...> \) is true, and

(13.2) \( \text{is-callable-from}<\text{VT} \) is true.

*Mandates:*

(14.1) \( \text{VT} \) is the same type as \( \text{T} \), and

(14.2) \( \text{is_copy_constructible_v}<\text{VT} \) is true.

*Preconditions:* \( \text{VT} \) meets the \text{Cpp17Destructible} and \text{Cpp17CopyConstructible} requirements.

*Postconditions:* \( \star\text{this} \) has a target object of type \( \text{VT} \) direct-non-list-initialized with \( \text{std::forward<}\text{Args}\>(\text{args})... \).

*Throws:* Any exception thrown by the initialization of the target object. May throw \text{bad_alloc} unless \( \text{VT} \) is a pointer or a specialization of \text{reference_wrapper}.

```cpp
template<class T, class U, class... Args>
explicit copyable_function(in_place_type_t<T>, initializer_list<U> ilist, Args&&... args);
```

Let \( \text{VT} \) be \( \text{decay_t}<\text{T} \).

*Constraints:*

(19.1) \( \text{is_constructible_v}<\text{VT}, \text{initializer_list<}\text{U}>&, \text{Args}...> \) is true, and

(19.2) \( \text{is-callable-from}<\text{VT} \) is true.

*Mandates:*

(20.1) \( \text{VT} \) is the same type as \( \text{T} \), and

(20.2) \( \text{is_copy_constructible_v}<\text{VT} \) is true.

*Preconditions:* \( \text{VT} \) meets the \text{Cpp17Destructible} and \text{Cpp17CopyConstructible} requirements.

*Postconditions:* \( \star\text{this} \) has a target object of type \( \text{VT} \) direct-non-list-initialized with \( \text{ilist}, \text{std::forward<}\text{Args}\>(\text{args})... \).

*Throws:* Any exception thrown by the initialization of the target object. May throw \text{bad_alloc} unless \( \text{VT} \) is a pointer or a specialization of \text{reference_wrapper}.

```cpp
\text{copyable_function}& \operator=(\text{const copyable_function}& f);
```

*Effects:* Equivalent to: \( \text{copyable_function}(f).\text{swap}(\star\text{this}) \).

*Returns:* \( \star\text{this} \).
copyable_function& operator=(copyable_function&& f);

    Effects: Equivalent to: copyable_function(std::move(f)).swap(*this);
    Returns: *this.

copyable_function& operator=(nullptr_t) noexcept;

    Effects: Destroys the target object of *this, if any.
    Returns: *this.

template<class F> copyable_function& operator=(F&& f);

    Effects: Equivalent to: copyable_function(std::forward<F>(f)).swap(*this);
    Returns: *this.

    ~copyable_function();

    Effects: Destroys the target object of *this, if any.

22.10.17.5.4 Invocation

    [func.wrap.copy.inv]

    explicit operator bool() const noexcept;

    Returns: true if *this has a target object, otherwise false.

    R operator()(ArgTypes... args) cv ref noexcept(noex);

    Preconditions: *this has a target object.
    Effects: Equivalent to:

        return INVOKE<R>(static_cast<F inv-quals>(f), std::forward<ArgTypes>(args)...);

    where f is an lvalue designating the target object of *this and F is the type of f.

22.10.17.5.5 Utility

    [func.wrap.copy.util]

    void swap(copyable_function& other) noexcept;

    Effects: Exchanges the target objects of *this and other.

    friend void swap(copyable_function& f1, copyable_function& f2) noexcept;

    Effects: Equivalent to f1.swap(f2).

    friend bool operator==(const copyable_function& f, nullptr_t) noexcept;

    Returns: true if f has no target object, otherwise false.

22.10.17.6 Non-owning wrapper

    [func.wrap.ref]

22.10.17.6.1 General

    [func.wrap.ref.general]

    The header provides partial specializations of function_ref for each combination of the possible replacements of the placeholders cv and noex where:

    (1.1) — cv is either const or empty, and
    (1.2) — noex is either true or false.

22.10.17.6.2 Class template function_ref

    [func.wrap.ref.class]

    namespace std {
        template<class R, class... ArgTypes>
        class function_ref<R(ArgTypes...) cv noexcept(noex)> { public:
        // 22.10.17.6.3, constructors and assignment operators
            template<class F> function_ref(F*) noexcept;
            template<class F> constexpr function_ref(F&&) noexcept;
            template<auto f> constexpr function_ref(nontype_t<f>) noexcept;
            template<auto f, class U> constexpr function_ref(nontype_t<f>, U&) noexcept;
            template<auto f, class T> constexpr function_ref(nontype_t<f>, cv T*) noexcept;
    803
constexpr function_ref(const function_ref&) noexcept = default;
constexpr function_ref& operator=(const function_ref&) noexcept = default;
template<class T> function_ref& operator=(T) = delete;

/// 22.10.17.6.4, invocation
R operator() (ArgTypes...) const noexcept(noex);

private:
  template<class... T>
  static constexpr bool is-invocable-using = see below; // exposition only
  R (*thunk-ptr) (BoundEntityType, Args&&...) noexcept(noex);
  BoundEntityType bound-entity; // exposition only
};

// 22.10.17.6.5, deduction guides
template<class F>
  function_ref(F*) -> function_ref<F>;
template<auto f>
  function_ref(nontype_t<f>) -> function_ref<see below>;
template<auto f, class T>
  function_ref(nontype_t<f>, T&&) -> function_ref<see below>;

// 22.10.17.6.6, constructors and assignment operators

template<class... T>
  static constexpr bool is-invocable-using = see below; // exposition only
  if noex is true, is-invocable-using<T...> is equal to:
    is_nothrow_invocable_r_v<R, T..., ArgTypes...>
  Otherwise, is-invocable-using<T...> is equal to:
    is_invocable_r_v<R, T..., ArgTypes...>

template<class F> function_ref(F* f) noexcept;

Constraints:
  — is_function_v<F> is true, and
  — is-invocable-using<F> is true.
Preconditions: f is not a null pointer.
Effects: Initializes bound-entity with f, and thunk-ptr with the address of a function thunk
such that thunk(bound-entity, call-args...) is expression-equivalent (3.20) to invoke_r<R>(f,
call-args...).

template<class F> constexpr function_ref(F&& f) noexcept;

Let T be remove_reference_t<F>.

Constraints:
  — remove_cvref_t<T> is not the same type as function_ref,
  — is_member_pointer_v<T> is false, and
  — is-invocable-using<cv T> is true.

1 An object of class function_ref<R(Args...) cv noexcept(noex)> stores a pointer to function thunk-ptr
and an object bound-entity. bound-entity has an unspecified trivially copyable type BoundEntityType,
that models copyable and is capable of storing a pointer to object value or a pointer to function value. The
type of thunk-ptr is R(*) (BoundEntityType, Args&&...) noexcept(noex).
2 Each specialization of function_ref is a trivially copyable type (6.8.1) that models copyable.
3 Within subclause 22.10.17.6, call-args is an argument pack with elements such that decltype((call-args
))... denote Args&&... respectively.

§ 22.10.17.6.3 804
Effects: Initializes `bound-entity` with `addressof(f)`, and `thunk-ptr` with the address of a function thunk such that `thunk(bound-entity, call-args...)` is expression-equivalent (3.20) to `invoke_r<R>(static_cast<cv T&>(f), call-args...)`.

```cpp
template<auto f> constexpr function_ref(nontype_t<f>) noexcept;
```

Constraints: `is-invocable-using<F>` is true.

Mandates: If `is_pointer_v<F> || is_member_pointer_v<F>` is true, then `f != nullptr` is true.

Effects: Initializes `bound-entity` with a pointer to an unspecified object or null pointer value, and `thunk-ptr` with the address of a function `thunk` such that `thunk(bound-entity, call-args...)` is expression-equivalent (3.20) to `invoke_r<R>(f, call-args...)`.

```cpp
template<auto f, class U> constexpr function_ref(nontype_t<f>, U&& obj) noexcept;
```

Constraints:

- `(13.1) is_rvalue_reference_v<U&&> is false, and`
- `(13.2) is-invocable-using<F, cv T*> is true.`

Mandates: If `is_pointer_v<F> || is_member_pointer_v<F>` is true, then `f != nullptr` is true.

Effects: Initializes `bound-entity` with `addressof(obj)` and `thunk-ptr` with the address of a function `thunk` such that `thunk(bound-entity, call-args...)` is expression-equivalent (3.20) to `invoke_r<R>(f, static_cast<cv T&>(obj), call-args...)`.

```cpp
template<class T> function_ref& operator=(T) = delete;
```

Constraints:

- `(21.1) T is not the same type as function_ref,`
- `(21.2) is_pointer_v<T> is false, and`
- `(21.3) T is not a specialization of nontype_t.`

22.10.17.6.4 Invocation

R operator()(ArgTypes... args) const noexcept(noex);

Effects: Equivalent to: return `thunk-ptr(bound-entity, std::forward<ArgTypes>(args)...)`;

22.10.17.6.5 Deduction guides

```cpp
template<class F> function_ref(F*) -> function_ref<F>;
```

Constraints: `is_function_v<F>` is true.

```cpp
template<auto f> function_ref(nontype_t<f>()) -> function_ref<see below>;
```

Constraints: `is_function_v<decltype(f)>` is true.
Remarks: The deduced type is `function_ref<F>`.

```cpp
template<auto f, class T>
function_ref(nontype_t<f>, T&&) -> function_ref<see below>;
```

Let `F` be `decltype(f)`.

Constraints:

(6.1) — `F` is of the form `R(G::*)(A...) cv &opt noexcept(E)` for a type `G`, or

(6.2) — `F` is of the form `M G::*` for a type `G` and an object type `M`, in which case let `R` be `invoke_result_t<F, T&>, A...` be an empty pack, and `E` be `false`, or

(6.3) — `F` is of the form `R(*)(G, A...) noexcept(E)` for a type `G`.

Remarks: The deduced type is `function_ref<R(A...) noexcept(E)>`.

### 22.10.18 Searchers

#### 22.10.18.1 General

Subclause 22.10.18 provides function object types (22.10) for operations that search for a sequence `[pat_first, pat_last)` in another sequence `[first, last)` that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in 22.10.18 shall meet the `Cpp17CopyConstructible` and `Cpp17CopyAssignable` requirements. Template parameters named

- ForwardIterator,
- ForwardIterator1,
- ForwardIterator2,
- RandomAccessIterator,
- RandomAccessIterator1,
- RandomAccessIterator2, and
- BinaryPredicate

of templates specified in 22.10.18 shall meet the same requirements and semantics as specified in 27.1. Template parameters named `Hash` shall meet the `Cpp17Hash` requirements (Table 37).

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

#### 22.10.18.2 Class template default_searcher

```cpp
namespace std {
    template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
    class default_searcher {
        public:
            constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                BinaryPredicate pred = BinaryPredicate());

            template<class ForwardIterator2>
            constexpr pair<ForwardIterator2, ForwardIterator2>
                operator()(ForwardIterator2 first, ForwardIterator2 last) const;

        private:
            ForwardIterator1 pat_first_; // exposition only
            ForwardIterator1 pat_last_; // exposition only
            BinaryPredicate pred_; // exposition only
    }
}
```
constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
    BinaryPredicate pred = BinaryPredicate());

Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_ with pat_last, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;

Effects: Returns a pair of iterators i and j such that

- i == search(first, last, pat_first_, pat_last_, pred_), and
- if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

22.10.18.3 Class template boyer_moore_searcher

namespace std {
    template<class RandomAccessIterator1, class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>, class BinaryPredicate = equal_to<>>
    class boyer_moore_searcher {
        public:
            boyer_moore_searcher(RandomAccessIterator1 pat_first,
                RandomAccessIterator1 pat_last,
                Hash hf = Hash(),
                BinaryPredicate pred = BinaryPredicate());

    template<class RandomAccessIterator2>
    pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

        private:
            RandomAccessIterator1 pat_first_; // exposition only
            RandomAccessIterator1 pat_last_; // exposition only
            Hash hash_; // exposition only
            BinaryPredicate pred_; // exposition only
    };}

boyer_moore_searcher(RandomAccessIterator1 pat_first,
    RandomAccessIterator1 pat_last,
    Hash hf = Hash(),
    BinaryPredicate pred = BinaryPredicate());

Preconditions: The value type of RandomAccessIterator1 meets the Cpp17DefaultConstructible, the Cpp17CopyConstructible, and the Cpp17CopyAssignable requirements.

Let V be iterator_traits<RandomAccessIterator1>::value_type. For any two values A and B of type V, if pred(A, B) == true, then hf(A) == hf(B) is true.

Effects: Initializes pat_first_ with pat_first, pat_last_ with pat_last, hash_ with hf, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1, or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

Mandates: RandomAccessIterator1 and RandomAccessIterator2 have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators i and j such that
— *i* is the first iterator in the range \([\text{first, last} - (\text{pat_last} - \text{pat_first})]\) such that for every non-negative integer \(n\) less than \(\text{pat_last} - \text{pat_first}\) the following condition holds:

\[
\text{pred}((i + n), *(\text{pat_first} + n)) \neq \text{false}, \text{and}
\]

(7.2)  
— \(j == \text{next}(i, \text{distance}(\text{pat_first}, \text{pat_last}))\).

Returns \(\text{make_pair(first, first)}\) if \([\text{pat_first, pat_last})\) is empty, otherwise returns \(\text{make_pair(last, last)}\) if no such iterator is found.

**Complexity:** At most \((\text{last} - \text{first}) \times (\text{pat_last} - \text{pat_first})\) applications of the predicate.

### 22.10.18.4 Class template boyer_moore_horspool_searcher

```cpp
namespace std {
    template<class RandomAccessIterator1, 
             class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>, 
             class BinaryPredicate = equal_to<>>
    class boyer_moore_horspool_searcher {
        public:
            boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first, 
                                           RandomAccessIterator1 pat_last, 
                                           Hash hf = Hash(), 
                                           BinaryPredicate pred = BinaryPredicate());

            template<class RandomAccessIterator2>
            pair<RandomAccessIterator2, RandomAccessIterator2> 
                operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
        private:
            RandomAccessIterator1 pat_first_;  // exposition only
            RandomAccessIterator1 pat_last_;   // exposition only
            Hash hash_;                       // exposition only
            BinaryPredicate pred_;            // exposition only
    };
}
```
Returns `make_pair(first, first)` if `pat_first_, pat_last_` is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

**Complexity**: At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

### 22.10.19 Class template `hash` [unord.hash]

The unordered associative containers defined in 24.5 use specializations of the class template `hash` (22.10.2) as the default hash function.

Each specialization of `hash` is either enabled or disabled, as described below.

[Note 1: Enabled specializations meet the `Cpp17Hash` requirements, and disabled specializations do not. — end note]

Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and pointer types. For any type `Key` for which neither the library nor the user provides an explicit or partial specialization of the class template `hash`, `hash<Key>` is disabled.

If the library provides an explicit or partial specialization of `hash<Key>`, that specialization is enabled except as noted otherwise, and its member functions are `noexcept` except as noted otherwise.

If `H` is a disabled specialization of `hash`, these values are `false`: `is_default_constructible_v<H>`, `is_copy_constructible_v<H>`, `is_move_constructible_v<H>`, `is_copy_assignable_v<H>`, and `is_move_assignable_v<H>`. Disabled specializations of `hash` are not function object types (22.10).

[Note 2: This means that the specialization of `hash` exists, but any attempts to use it as a `Cpp17Hash` will be ill-formed. — end note]

An enabled specialization `hash<Key>` will:

1. meet the `Cpp17Hash` requirements (Table 37), with `Key` as the function call argument type, the `Cpp17DefaultConstructible` requirements (Table 30), the `Cpp17CopyAssignable` requirements (Table 34), the `Cpp17Swappable` requirements (16.4.4.3),
2. meet the requirement that if `k1 == k2` is `true`, `h(k1) == h(k2)` is also `true`, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;
3. meet the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization.

### 22.11 Class `type_index` [type.index]

#### 22.11.1 Header `<typeindex>` synopsis [type.index.synopsis]

```cpp
#include <compare> // see 17.11.1

namespace std {
    class type_index;
    template<class T> struct hash;
    template<> struct hash<type_index>;
}
```

#### 22.11.2 `type_index` overview [type.index.overview]

```cpp
namespace std {
    class type_index {
        public:
            type_index(const type_info& rhs) noexcept;
            bool operator==(const type_info& rhs) const noexcept;
            bool operator<(const type_info& rhs) const noexcept;
            bool operator>(const type_info& rhs) const noexcept;
            bool operator<=(const type_info& rhs) const noexcept;
            bool operator>=(const type_info& rhs) const noexcept;
            strong_ordering operator<=>(const type_info& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;
            const type_info* target; // exposition only
    }
```
The class `type_index` provides a simple wrapper for `type_info` which can be used as an index type in associative containers (24.4) and in unordered associative containers (24.5).

### 22.11.3 `type_index` members

- `type_index(const type_info& rhs) noexcept;`  
  **Effects:** Constructs a `type_index` object, the equivalent of `target = &rhs`.

- `bool operator==(const type_index& rhs) const noexcept;`  
  **Returns:** `*target == *rhs.target`.

- `bool operator<(const type_index& rhs) const noexcept;`  
  **Returns:** `target->before(*rhs.target)`.

- `bool operator>(const type_index& rhs) const noexcept;`  
  **Returns:** `rhs.target->before(*target)`.

- `bool operator<=(const type_index& rhs) const noexcept;`  
  **Returns:** `!rhs.target->before(*target)`.

- `bool operator>=(const type_index& rhs) const noexcept;`  
  **Returns:** `!target->before(*rhs.target)`.

- `strong_ordering operator<=>(const type_index& rhs) const noexcept;`  
  **Effects:** Equivalent to:
  ```
  if (*target == *rhs.target) return strong_ordering::equal;
  if (target->before(*rhs.target)) return strong_ordering::less;
  return strong_ordering::greater;
  ```

- `size_t hash_code() const noexcept;`  
  **Returns:** `target->hash_code()`.

- `const char* name() const noexcept;`  
  **Returns:** `target->name()`.

### 22.11.4 Hash support

- `template<> struct hash<type_index>;`  
  For an object `index` of type `type_index`, `hash<type_index>()(index)` shall evaluate to the same result as `index.hash_code()`.

### 22.12 Execution policies

#### 22.12.1 In general

Subclause 22.12 describes classes that are `execution policy` types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions.

**Example 1:**
```
using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());
```
// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());

—end example

[Note 1: Implementations can provide additional execution policies to those described in this standard as extensions to address parallel architectures that require idiosyncratic parameters for efficient execution. —end note]

### 22.12.2 Header `<execution>` synopsis

```cpp
namespace std {
  // 22.12.3, execution policy type trait
  template<class T> struct is_execution_policy;
  template<class T> constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}
namespace std::execution {
  // 22.12.4, sequenced execution policy
  class sequenced_policy;
  // 22.12.5, parallel execution policy
  class parallel_policy;
  // 22.12.6, parallel and unsequenced execution policy
  class parallel_unsequenced_policy;
  // 22.12.7, unsequenced execution policy
  class unsequenced_policy;
  // 22.12.8, execution policy objects
  inline constexpr sequenced_policy seq{ unspecified };  
  inline constexpr parallel_policy par{ unspecified };  
  inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };  
  inline constexpr unsequenced_policy unseq{ unspecified };  
}
```

### 22.12.3 Execution policy type trait

```cpp
template<class T> struct is_execution_policy { see below };  

1. `is_execution_policy` can be used to detect execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

2. `is_execution_policy<T>` is a `Cpp17UnaryTypeTrait` with a base characteristic of `true_type` if T is the type of a standard or implementation-defined execution policy, otherwise `false_type`.

[Note 1: This provision reserves the privilege of creating non-standard execution policies to the library implementation. —end note]

3. The behavior of a program that adds specializations for `is_execution_policy` is undefined.

### 22.12.4 Sequenced execution policy

```cpp
class execution::sequenced_policy { unspecified };  

1. The class `execution::sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

2. During the execution of a parallel algorithm with the `execution::sequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

§ 22.12.4
22.12.5 Parallel execution policy

The class `execution::parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized.

During the execution of a parallel algorithm with the `execution::parallel_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.6 Parallel and unsequenced execution policy

The class `execution::parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be parallelized and vectorized.

During the execution of a parallel algorithm with the `execution::parallel_unsequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.7 Unsequenced execution policy

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm's execution may be vectorized, e.g., executed on a single thread using instructions that operate on multiple data items.

During the execution of a parallel algorithm with the `execution::unsequenced_policy` policy, if the invocation of an element access function exits via an exception, `terminate` is invoked (14.6.2).

22.12.8 Execution policy objects

The header `<execution>` declares global objects associated with each type of execution policy.

22.13 Primitive numeric conversions

When a function is specified with a type placeholder of `integer-type`, the implementation provides overloads for all cv-unqualified signed and unsigned integer types and `char` in lieu of `integer-type`. When a function is specified with a type placeholder of `floating-point-type`, the implementation provides overloads for all cv-unqualified floating-point types (6.8.2) in lieu of `floating-point-type`.

```
namespace std {
    // floating-point format for primitive numerical conversion
    enum class chars_format {
        scientific = unspecified,
        fixed = unspecified,
        hex = unspecified,
        general = fixed | scientific
    };

    // 22.13.2, primitive numerical output conversion
    struct to_chars_result {
        // freestanding
        char* ptr;
        errc ec;
        friend bool operator==(const to_chars_result&, const to_chars_result&) = default;
        constexpr explicit operator bool() const noexcept { return ec == errc{ }; }
    };
}
```
constexpr to_chars_result to_chars(char* first, char* last,
    integer-type value, int base = 10);  // freestanding

to_chars_result to_chars(char* first, char* last,
    bool value, int base = 10) = delete;  // freestanding-deleted

to_chars_result to_chars(char* first, char* last,
    floating-point-type value);  // freestanding-deleted

to_chars_result to_chars(char* first, char* last,
    floating-point-type value, chars_format fmt);  // freestanding-deleted

to_chars_result to_chars(char* first, char* last,
    floating-point-type value, chars_format fmt, int precision);  // freestanding-deleted

// 22.13.3, primitive numerical input conversion
struct from_chars_result {  // freestanding
    const char* ptr;
    errc ec;
};

constexpr explicit operator bool() const noexcept { return ec == errc{}; }

constexpr from_chars_result from_chars(const char* first, const char* last,
    integer-type& value, int base = 10);  // freestanding

from_chars_result from_chars(const char* first, const char* last,
    floating-point-type& value,
    chars_format fmt = chars_format::general);  // freestanding-deleted

2 The type chars_format is a bitmask type (16.3.3.3.3) with elements scientific, fixed, and hex.
3 The types to_chars_result and from_chars_result have the data members and special members specified
   above. They have no base classes or members other than those specified.

22.13.2 Primitive numeric output conversion [charconv.to.chars]

All functions named to_chars convert value into a character string by successively filling the range
[first, last), where [first, last) is required to be a valid range. If the member ec of the return value
is such that the value is equal to the value of a value-initialized errc, the conversion was successful and
the member ptr is the one-past-the-end pointer of the characters written. Otherwise, the member ec has
the value errc::value_too_large, the member ptr has the value last, and the contents of the range
[first, last) are unspecified.

2 The functions that take a floating-point value but not a precision parameter ensure that the string
representation consists of the smallest number of characters such that there is at least one digit before the
radix point (if present) and parsing the representation using the corresponding from_chars function recovers
value exactly.

[Note 1: This guarantee applies only if to_chars and from_chars are executed on the same implementation. — end
note]

If there are several such representations, the representation with the smallest difference from the floating-
point argument value is chosen, resolving any remaining ties using rounding according to round_to_nearest (17.3.4).

3 The functions taking a chars_format parameter determine the conversion specifier for printf as follows:
The conversion specifier is f if fmt is chars_format::fixed, e if fmt is chars_format::scientific, a
(without leading "0x" in the result) if fmt is chars_format::hex, and g if fmt is chars_format::general.

4 Preconditions: base has a value between 2 and 36 (inclusive).

5 Effects: The value of value is converted to a string of digits in the given base (with no redundant
leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If
value is less than zero, the representation starts with '−'.

6 Throws: Nothing.
to_chars_result to_chars(char* first, char* last, floating-point-type value);

Effects: value is converted to a string in the style of printf in the "C" locale. The conversion specifier is f or e, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of f.

Throws: Nothing.

to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt);

Preconditions: fmt has the value of one of the enumerators of chars_format.

Effects: value is converted to a string in the style of printf in the "C" locale.

Throws: Nothing.

to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt, int precision);

Preconditions: fmt has the value of one of the enumerators of chars_format.

Effects: value is converted to a string in the style of printf in the "C" locale with the given precision.

Throws: Nothing.

See also: ISO/IEC 9899:2018, 7.21.6.1

22.13.3 Primitive numeric input conversion [charconv.from.chars]

All functions named from_chars analyze the string [first, last) for a pattern, where [first, last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument.

[Note 1: If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern. — end note]

Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and the member ec of the return value is equal to errc::result_out_of_range. Otherwise, value is set to the parsed value, after rounding according to round_to_nearest (17.3.4), and the member ec is value-initialized.

constexpr from_chars_result from_chars(const char* first, const char* last, integer-type& value, int base = 10);

Preconditions: base has a value between 2 and 36 (inclusive).

Effects: The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for strtol, except that no "0x" or "0X" prefix shall appear if the value of base is 16, and except that '+' is the only sign that may appear, and only if value has a signed type.

Throws: Nothing.

from_chars_result from_chars(const char* first, const char* last, floating-point-type& value, chars_format fmt = chars_format::general);

Preconditions: fmt has the value of one of the enumerators of chars_format.

Effects: The pattern is the expected form of the subject sequence in the "C" locale, as described for strtod, except that

(6.1) the sign '+' may only appear in the exponent part;

(6.2) if fmt has chars_format::scientific set but not chars_format::fixed, the otherwise optional exponent part shall appear;

(6.3) if fmt has chars_format::fixed set but not chars_format::scientific, the optional exponent part shall not appear; and

(6.4) if fmt is chars_format::hex, the prefix "0x" or "0X" is assumed.

[Example 1: The string 0x123 is parsed to have the value 0 with remaining characters x123. — end example]
In any case, the resulting value is one of at most two floating-point values closest to the value of the string matching the pattern.

**Throws**: Nothing.

**See also**: ISO/IEC 9899:2018, 7.22.1.3, 7.22.1.4

### 22.14 Formatting

#### 22.14.1 Header `<format>` synopsis

```cpp
namespace std {
    // 22.14.6.6, class template basic_format_context
    template<Out, class charT> class basic_format_context;
    using format_context = basic_format_context<unspecified, char>;
    using wformat_context = basic_format_context<unspecified, wchar_t>;

    // 22.14.8.3, class template basic_format_args
    template<Context> class basic_format_args;
    using format_args = basic_format_args<format_context>;
    using wformat_args = basic_format_args<wformat_context>;

1 The class template format_to_n_result has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

22.14.2 Format string

22.14.2.1 In general

1 A format string for arguments args is a (possibly empty) sequence of replacement fields, escape sequences, and characters other than { and }. Let charT be the character type of the format string. Each character that is not part of a replacement field or an escape sequence is copied unchanged to the output. An escape sequence is one of { or }. It is replaced with { or }, respectively, in the output. The syntax of replacement fields is as follows:

replacement-field:
  { arg-id \opt format-specifier \opt }

arg-id:
  0
  positive-integer

§ 22.14.2.1
positive-integer:
  nonzero-digit
positive-integer digit
nonnegative-integer:
  digit
nonnegative-integer digit
nonzero-digit: one of
  1 2 3 4 5 6 7 8 9
digit: one of
  0 1 2 3 4 5 6 7 8 9
format-specifier:
  : format-spec
format-spec:
  as specified by the formatter specialization for the argument type; cannot start with }

2 The arg-id field specifies the index of the argument in args whose value is to be formatted and inserted into the output instead of the replacement field. If there is no argument with the index arg-id in args, the string is not a format string for args. The optional format-specifier field explicitly specifies a format for the replacement value.

3 [Example 1]:

```c
string s = format("{0}-{1}", 8);  // value of s is "8-"
```
—end example]  

4 If all arg-ids in a format string are omitted (including those in the format-spec, as interpreted by the corresponding formatter specialization), argument indices 0, 1, 2, ... will automatically be used in that order. If some arg-ids are omitted and some are present, the string is not a format string.

[Note 1: A format string cannot contain a mixture of automatic and manual indexing. — end note]

[Example 2]:

```c
string s0 = format("{} to {}", "a", "b");  // OK, automatic indexing
string s1 = format("{1} to {0}", "a", "b");  // OK, manual indexing
string s2 = format("{0} to {}", "a", "b");  // not a format string (mixing automatic and manual indexing),
  // ill-formed
string s3 = format("{} to {1}", "a", "b");  // not a format string (mixing automatic and manual indexing),
  // ill-formed
```
—end example]

5 The format-spec field contains format specifications that define how the value should be presented. Each type can define its own interpretation of the format-spec field. If format-spec does not conform to the format specifications for the argument type referred to by arg-id, the string is not a format string for args.

[Example 3]:

(5.1) — For arithmetic, pointer, and string types the format-spec is interpreted as a std-format-spec as described in (22.14.2.2).

(5.2) — For chrono types the format-spec is interpreted as a chrono-format-spec as described in (29.12).

(5.3) — For user-defined formatter specializations, the behavior of the parse member function determines how the format-spec is interpreted.
—end example]

22.14.2.2 Standard format specifiers

[format.string.std]

1 Each formatter specialization described in 22.14.6.3 for fundamental and string types interprets format-spec as a std-format-spec.

[Note 1: The format specification can be used to specify such details as minimum field width, alignment, padding, and decimal precision. Some of the formatting options are only supported for arithmetic types. — end note]

The syntax of format specifications is as follows:

```
std-format-spec:
  fill-and-align_opt sign_opt #_opt 0_opt width_opt precision_opt L_opt type_opt
```
fill-and-align:
  fill_opt align
fill:
  any character other than { or }
align: one of
  < > ^
sign: one of
  + - space
width:
  positive-integer
    { arg-id_opt }
precision:
  . nonnegative-integer
    { arg-id_opt }
type: one of
  a A b B c d e E f F g G o p P s x X ?

2 Field widths are specified in field width units; the number of column positions required to display a sequence of characters in a terminal. The minimum field width is the number of field width units a replacement field minimally requires of the formatted sequence of characters produced for a format argument. The estimated field width is the number of field width units that are required for the formatted sequence of characters produced for a format argument independent of the effects of the width option. The padding width is the greater of 0 and the difference of the minimum field width and the estimated field width.

[Note 2: The POSIX wcswidth function is an example of a function that, given a string, returns the number of column positions required by a terminal to display the string. —end note]

3 The fill character is the character denoted by the fill option or, if the fill option is absent, the space character. For a format specification in UTF-8, UTF-16, or UTF-32, the fill character corresponds to a single Unicode scalar value.

[Note 3: The presence of a fill option is signaled by the character following it, which must be one of the alignment options. If the second character of std-format-spec is not a valid alignment option, then it is assumed that the fill and align options are both absent. —end note]

4 The align option applies to all argument types. The meaning of the various alignment options is as specified in Table 65.

[Example 1:
  char c = 120;
  string s0 = format("{:6}", 42); // value of s0 is " 42"
  string s1 = format("{:6}", 'x'); // value of s1 is "x "
  string s2 = format("{:<6}", 'x'); // value of s2 is "x*****"
  string s3 = format("{:>6}", 'x'); // value of s3 is "*****x"
  string s4 = format("{:*<6}", 'x'); // value of s4 is "**x***"
  string s5 = format("{:6d}" , c); // value of s5 is " 120"
  string s6 = format("{:6}" , true); // value of s6 is "true "
  string s7 = format("{:<6.3}" , "123456"); // value of s7 is "123***"
  string s8 = format("{:02}" , 1234); // value of s8 is "1234"
  string s9 = format("{:<}" , "12"); // value of s9 is "12"
  string sa = format("{:<6}" , "12345678"); // value of sa is "12345678"
  string sb = format("{:<6}" , "x"); // value of sb is "x*****"
  string sc = format("{:<6}", "x"); // value of sc is "x******"
  —end example]

[Note 4: The fill, align, and 0 options have no effect when the minimum field width is not greater than the estimated field width because padding width is 0 in that case. Since fill characters are assumed to have a field width of 1, use of a character with a different field width can produce misaligned output. The 🤡 (U+1F921 clown face) character has a field width of 2. The examples above that include that character illustrate the effect of the field width when that character is used as a fill character as opposed to when it is used as a formatting argument. —end note]

5 The sign option is only valid for arithmetic types other than charT and bool or when an integer presentation type is specified. The meaning of the various options is as specified in Table 66.

6 The sign option applies to floating-point infinity and NaN.
### Table 65 — Meaning of `align` options [tab:format.align]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td>Forces the formatted argument to be aligned to the start of the field by inserting ( n ) fill characters after the formatted argument where ( n ) is the padding width. This is the default for non-arithmetic non-pointer types, <code>charT</code>, and <code>bool</code>, unless an integer presentation type is specified.</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>Forces the formatted argument to be aligned to the end of the field by inserting ( n ) fill characters before the formatted argument where ( n ) is the padding width. This is the default for arithmetic types other than <code>charT</code> and <code>bool</code>, pointer types, or when an integer presentation type is specified.</td>
</tr>
<tr>
<td><code>-</code></td>
<td>Forces the formatted argument to be centered within the field by inserting ( \left\lfloor \frac{n}{2} \right\rfloor ) fill characters before and ( \left\lceil \frac{n}{2} \right\rceil ) fill characters after the formatted argument, where ( n ) is the padding width.</td>
</tr>
</tbody>
</table>

### Table 66 — Meaning of `sign` options [tab:format.sign]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+</code></td>
<td>Indicates that a sign should be used for both non-negative and negative numbers. The + sign is inserted before the output of <code>to_chars</code> for non-negative numbers other than negative zero.</td>
</tr>
<tr>
<td></td>
<td>[Note 5: For negative numbers and negative zero the output of <code>to_chars</code> will already contain the sign so no additional transformation is performed. — end note]</td>
</tr>
<tr>
<td><code>-</code></td>
<td>Indicates that a sign should be used for negative numbers and negative zero only (this is the default behavior).</td>
</tr>
<tr>
<td><code>space</code></td>
<td>Indicates that a leading space should be used for non-negative numbers other than negative zero, and a minus sign for negative numbers and negative zero.</td>
</tr>
</tbody>
</table>

---

7 The `#` option causes the alternate form to be used for the conversion. This option is valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified, and not otherwise. For integral types, the alternate form inserts the base prefix (if any) specified in Table 68 into the output after the sign character (possibly space) if there is one, or before the output of `to_chars` otherwise. For floating-point types, the alternate form causes the result of the conversion of finite values to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for `g` and `G` conversions, trailing zeros are not removed from the result.

8 The `0` option is valid for arithmetic types other than `charT` and `bool`, pointer types, or when an integer presentation type is specified. For formatting arguments that have a value other than an infinity or a NaN, this option pads the formatted argument by inserting the 0 character \( n \) times following the sign or base prefix indicators (if any) where \( n \) is 0 if the `align` option is present and is the padding width otherwise.
The width option specifies the minimum field width. If the width option is absent, the minimum field width is 0.

If \{ arg-id_opt \} is used in a width or precision option, the value of the corresponding formatting argument is used as the value of the option. The option is valid only if the corresponding formatting argument is of standard signed or unsigned integer type. If its value is negative, an exception of type format_error is thrown.

If positive-integer is used in a width option, the value of the positive-integer is interpreted as a decimal integer and used as the value of the option.

For the purposes of width computation, a string is assumed to be in a locale-independent, implementation-defined encoding. Implementations should use either UTF-8, UTF-16, or UTF-32, on platforms capable of displaying Unicode text in a terminal.

[Note 6: This is the case for Windows®-based and many POSIX-based operating systems. — end note]

For a sequence of characters in UTF-8, UTF-16, or UTF-32, an implementation should use as its field width the sum of the field widths of the first code point of each extended grapheme cluster. Extended grapheme clusters are defined by UAX #29 of the Unicode Standard. The following code points have a field width of 2:

- any code point with the East_Asian_Width="W" or East_Asian_Width="F" Derived Extracted Property as described by UAX #44 of the Unicode Standard
- U+4DC0 – U+4DFF (Yijing Hexagram Symbols)
- U+1F300 – U+1F5FF (Miscellaneous Symbols and Pictographs)
- U+1F900 – U+1F9FF (Supplemental Symbols and Pictographs)

The field width of all other code points is 1.

For a sequence of characters in neither UTF-8, UTF-16, nor UTF-32, the field width is unspecified.

The precision option is valid for floating-point and string types. For floating-point types, the value of this option specifies the precision to be used for the floating-point presentation type. For string types, this option specifies the longest prefix of the formatted argument to be included in the replacement field such that the field width of the prefix is no greater than the value of this option.

If nonnegative-integer is used in a precision option, the value of the decimal integer is used as the value of the option.

When the L option is used, the form used for the conversion is called the locale-specific form. The L option is only valid for arithmetic types, and its effect depends upon the type.

- For integral types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group separator characters.
- For floating-point types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group and radix separator characters.
- For the textual representation of bool, the locale-specific form causes the context’s locale to be used to insert the appropriate string as if obtained with numpunct::truename or numpunct::falsename.

The type determines how the data should be presented.

The available string presentation types are specified in Table 67.

### Table 67 — Meaning of type options for strings

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none, s</td>
<td>Copies the string to the output.</td>
</tr>
<tr>
<td>?</td>
<td>Copies the escaped string (22.14.6.4) to the output.</td>
</tr>
</tbody>
</table>

The meaning of some non-string presentation types is defined in terms of a call to to_chars. In such cases, let [first,last) be a range large enough to hold the to_chars output and value be the formatting argument.
value. Formatting is done as if by calling `to_chars` as specified and copying the output through the output iterator of the format context.

[Note 7: Additional padding and adjustments are performed prior to copying the output through the output iterator as specified by the format specifiers. — end note]

The available integer presentation types for integral types other than `bool` and `charT` are specified in Table 68.

[Example 4:

```cpp
string s0 = format("{}", 42); // value of s0 is "42"
string s1 = format("{0:b} {0:d} {0:o} {0:x}", 42); // value of s1 is "101010 42 52 2a"
string s2 = format("{0:#x} {0:#X}", 42); // value of s2 is "0x2a 0X2A"
string s3 = format("{:L}", 1234); // value of s3 can be "1,234" // (depending on the locale)
```

— end example]

### Table 68 — Meaning of type options for integer types [tab:format.type.int]

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>b</code></td>
<td><code>to_chars(first, last, value, 2);</code> the base prefix is <code>0b</code>.</td>
</tr>
<tr>
<td><code>B</code></td>
<td>The same as <code>b</code>, except that the base prefix is <code>0B</code>.</td>
</tr>
<tr>
<td><code>c</code></td>
<td>Copies the character <code>static_cast&lt;charT&gt;(value)</code> to the output. Throws <code>format_error</code> if <code>value</code> is not in the range of representable values for <code>charT</code>.</td>
</tr>
<tr>
<td><code>d</code></td>
<td><code>to_chars(first, last, value);</code>.</td>
</tr>
<tr>
<td><code>o</code></td>
<td><code>to_chars(first, last, value, 8);</code> the base prefix is <code>0</code> if <code>value</code> is nonzero and is empty otherwise.</td>
</tr>
<tr>
<td><code>x</code></td>
<td><code>to_chars(first, last, value, 16);</code> the base prefix is <code>0x</code>.</td>
</tr>
<tr>
<td><code>X</code></td>
<td>The same as <code>x</code>, except that it uses uppercase letters for digits above 9 and the base prefix is <code>0X</code>.</td>
</tr>
<tr>
<td><code>none</code></td>
<td>The same as <code>d</code>.</td>
</tr>
</tbody>
</table>

[Note 8: If the formatting argument type is `charT` or `bool`, the default is instead `c` or `s`, respectively. — end note]

The available `charT` presentation types are specified in Table 69.

### Table 69 — Meaning of type options for `charT` [tab:format.type.char]

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>b</code>, <code>B</code>, <code>d</code>, <code>o</code>, <code>x</code>, <code>X</code></td>
<td>As specified in Table 68 with <code>value</code> converted to the unsigned version of the underlying type.</td>
</tr>
<tr>
<td><code>?</code></td>
<td>Copies the escaped character (22.14.6.4) to the output.</td>
</tr>
</tbody>
</table>

The available `bool` presentation types are specified in Table 70.

### Table 70 — Meaning of type options for `bool` [tab:format.type.bool]

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>b</code>, <code>B</code>, <code>d</code>, <code>o</code>, <code>x</code>, <code>X</code></td>
<td>As specified in Table 68 for the value <code>static_cast&lt;unsigned char&gt;(value)</code>.</td>
</tr>
</tbody>
</table>

The available floating-point presentation types and their meanings for values other than infinity and NaN are specified in Table 71. For lower-case presentation types, infinity and NaN are formatted as `inf` and `nan`, respectively. For upper-case presentation types, infinity and NaN are formatted as `INF` and `NAN`, respectively.

[Note 9: In either case, a sign is included if indicated by the `sign` option. — end note]

The available pointer presentation types and their mapping to `to_chars` are specified in Table 72.

[Note 10: Pointer presentation types also apply to `nullptr_t`. — end note]
<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>If <code>precision</code> is specified, equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::hex, precision)</code> where <code>precision</code> is the specified formatting precision; equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::hex)</code> otherwise.</td>
</tr>
<tr>
<td>A</td>
<td>The same as a, except that it uses uppercase letters for digits above 9 and P to indicate the exponent.</td>
</tr>
<tr>
<td>e</td>
<td>Equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::scientific, precision)</code> where <code>precision</code> is the specified formatting precision, or 6 if <code>precision</code> is not specified.</td>
</tr>
<tr>
<td>E</td>
<td>The same as e, except that it uses E to indicate exponent.</td>
</tr>
<tr>
<td>f</td>
<td>Equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::fixed, precision)</code> where <code>precision</code> is the specified formatting precision, or 6 if <code>precision</code> is not specified.</td>
</tr>
<tr>
<td>F</td>
<td>The same as f, except that it uses E to indicate exponent.</td>
</tr>
<tr>
<td>g</td>
<td>Equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::general, precision)</code> where <code>precision</code> is the specified formatting precision, or 6 if <code>precision</code> is not specified.</td>
</tr>
<tr>
<td>G</td>
<td>The same as g, except that it uses E to indicate exponent.</td>
</tr>
<tr>
<td>none</td>
<td>If <code>precision</code> is specified, equivalent to &lt;br&gt; <code>to_chars(first, last, value, chars_format::general, precision)</code> where <code>precision</code> is the specified formatting precision; equivalent to &lt;br&gt; <code>to_chars(first, last, value)</code> otherwise.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>If <code>uintptr_t</code> is defined, &lt;br&gt; <code>to_chars(first, last, reinterpret_cast&lt;uintptr_t&gt;(value), 16)</code> with the prefix 0x inserted immediately before the output of <code>to_chars</code>; otherwise, implementation-defined.</td>
</tr>
<tr>
<td>P</td>
<td>The same as p, except that it uses uppercase letters for digits above 9 and the base prefix is 0X.</td>
</tr>
</tbody>
</table>

### 22.14.3 Error reporting

Formatting functions throw `format_error` if an argument `fmt` is passed that is not a format string for `args`. They propagate exceptions thrown by operations of `formatter` specializations and iterators. Failure to allocate storage is reported by throwing an exception as described in 16.4.6.13.

### 22.14.4 Class template `basic_format_string`

```cpp
namespace std {
    template<class charT, class... Args>
    struct basic_format_string {
        private:
            basic_string_view<charT> str; // exposition only

        public:
            template<class T> constexpr basic_format_string(const T& s) {
                str = runtime_format_string<charT>(s).get();
            }

            constexpr basic_string_view<charT> get() const noexcept { return str; }
    };
}
```
template<class T> consteval basic_format_string(const T& s);

Constraints: const T& models convertible_to<basic_string_view<charT>>.

Effects: Direct-non-list-initializes str with s.

Remarks: A call to this function is not a core constant expression (7.7) unless there exist args of types Args such that str is a format string for args.

22.14.5 Formatting functions

In the description of the functions, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of a + n are the same as in 27.2.

template<class... Args>
string format(format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat(fmt.str, make_format_args(args...));

template<class... Args>
wstring format(wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat(fmt.str, make_wformat_args(args...));

template<class... Args>
string format(const locale& loc, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat(loc, fmt.str, make_format_args(args...));

template<class... Args>
wstring format(const locale& loc, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat(loc, fmt.str, make_wformat_args(args...));

string vformat(string_view fmt, format_args args);
wstring vformat(wstring_view fmt, wformat_args args);
string vformat(const locale& loc, string_view fmt, format_args args);
wstring vformat(const locale& loc, wstring_view fmt, wformat_args args);

Returns: A string object holding the character representation of formatting arguments provided by args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 22.14.3.

template<class Out, class... Args>
Out format_to(Out out, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat_to(std::move(out), fmt.str, make_format_args(args...));

template<class Out, class... Args>
Out format_to(Out out, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat_to(std::move(out), fmt.str, make_wformat_args(args...));

template<class Out, class... Args>
Out format_to(Out out, const locale& loc, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat_to(std::move(out), loc, fmt.str, make_format_args(args...));

template<class Out, class... Args>
Out format_to(Out out, const locale& loc, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat_to(std::move(out), loc, fmt.str, make_wformat_args(args...));

template<class Out>
Out vformat_to(Out out, string_view fmt, format_args args);

template<class Out>
Out vformat_to(Out out, wstring_view fmt, wformat_args args);

template<class Out>
Out vformat_to(Out out, const locale& loc, string_view fmt, format_args args);

template<class Out>
Out vformat_to(Out out, const locale& loc, wstring_view fmt, wformat_args args);

Let charT be decltype(fmt)::value_type.

Constraints: Out satisfies output_iterator<const charT&>.

Preconditions: Out models output_iterator<const charT&>.

Effects: Places the character representation of formatting the arguments provided by args, formatted according to the specifications given in fmt, into the range [out, out + N], where N is the number of characters in that character representation. If present, loc is used for locale-specific formatting.

Returns: out + N.

Throws: As specified in 22.14.3.

Let

— charT be decltype(fmt.str)::value_type,
— N be formatted_size(fmt, args...) for the functions without a loc parameter and formatted_size(loc, fmt, args...) for the functions with a loc parameter, and
— M be clamp(n, 0, N).

Constraints: Out satisfies output_iterator<const charT&>.

Preconditions: Out models output_iterator<const charT&>, and formatter<remove_cvref_t<T>, charT> meets the BasicFormatter requirements (22.14.6.1) for each T, in Args.

Effects: Places the first M characters of the character representation of formatting the arguments provided by args, formatted according to the specifications given in fmt, into the range [out, out + M]. If present, loc is used for locale-specific formatting.

Returns: {out + M, N}.

Throws: As specified in 22.14.3.

Let charT be decltype(fmt.str)::value_type.

§ 22.14.5
Preconditions: formatter<remove_cvref_t<T>, charT> meets the BasicFormatter requirements (22.14.6.1) for each T_i in Args.

Returns: The number of characters in the character representation of formatting arguments args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 22.14.3.

22.14.6 Formatter

22.14.6.1 Formatter requirements

1 A type F meets the BasicFormatter requirements if it meets the
   (1.1) — Cpp17DefaultConstructible (Table 30),
   (1.2) — Cpp17CopyConstructible (Table 32),
   (1.3) — Cpp17CopyAssignable (Table 34),
   (1.4) — Cpp17Swappable (16.4.4.3), and
   (1.5) — Cpp17Destructible (Table 35)
   requirements, and the expressions shown in Table 73 are valid and have the indicated semantics.

2 A type F meets the Formatter requirements if it meets the BasicFormatter requirements and the expressions shown in Table 74 are valid and have the indicated semantics.

3 Given character type charT, output iterator type Out, and formatting argument type T, in Table 73 and Table 74:
   (3.1) — f is a value of type (possibly const) F,
   (3.2) — g is an lvalue of type F,
   (3.3) — u is an lvalue of type T,
   (3.4) — t is a value of a type convertible to (possibly const) T,
   (3.5) — PC is basic_format_parse_context<charT>,
   (3.6) — FC is basic_format_context<Out, charT>,
   (3.7) — pc is an lvalue of type PC, and
   (3.8) — fc is an lvalue of type FC.

   pc.begin() points to the beginning of the format-spec (22.14.2) of the replacement field being formatted in the format string. If format-spec is not present or empty then either pc.begin() == pc.end() or *pc.begin() == '}'.

22.14.6.2 Concept formattable

1 Let fmt-iter-for<charT> be an unspecified type that models output_iterator<const charT&> (25.3.4.10).

   template<class T, class Context, 
   class Formatter = typename Context::template formatter_type<remove_const_t<T>>>
   concept formattable-with = 
   // exposition only 
   semiregular<Formatter> &&
   requires(Formatter& f, const Formatter& cf, T&& t, Context fc,
           basic_format_parse_context<typename Context::char_type> pc)
   {
       { f.parse(pc) } -> same_as<typename decltype(pc)::iterator>;
       { cf.format(t, fc) } -> same_as<typename Context::iterator>;
   };

   template<class T, class charT>
   concept formattable =
   formattable-with<remove_reference_t<T>, basic_format_context<fmt-iter-for<charT>, charT>>;

2 A type T and a character type charT model formattable if formatter<remove_cvref_t<T>, charT> meets the BasicFormatter requirements (22.14.6.1) and, if remove_reference_t<T> is const-qualified, the Formatter requirements.
### Table 73 — BasicFormatter requirements [tab:formatter.basic]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
</table>
| `g.parse(pc)` | `PC::iterator` | Parses `format-spec` (22.14.2) for type `T` in the range `[pc.begin(), pc.end())` until the first unmatched character. Throws `format_error` unless the whole range is parsed or the unmatched character is `.`. 

[Note 1: This allows formatters to emit meaningful error messages. — end note] Stores the parsed format specifiers in `*this` and returns an iterator past the end of the parsed range. |

| `f.format(u, fc)` | `FC::iterator` | Formats `u` according to the specifiers stored in `*this`, writes the output to `fc.out()`, and returns an iterator past the end of the output range. The output shall only depend on `u`, `fc.locale()`, `fc.arg(n)` for any value `n` of type `size_t`, and the range `[pc.begin(), pc.end())` from the last call to `f.parse(pc)`. |

### Table 74 — Formatter requirements [tab:formatter]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>f.format(t, fc)</code></td>
<td><code>FC::iterator</code></td>
<td>Formats <code>t</code> according to the specifiers stored in <code>*this</code>, writes the output to <code>fc.out()</code>, and returns an iterator past the end of the output range. The output shall only depend on <code>t</code>, <code>fc.locale()</code>, <code>fc.arg(n)</code> for any value <code>n</code> of type <code>size_t</code>, and the range <code>[pc.begin(), pc.end())</code> from the last call to <code>f.parse(pc)</code>.</td>
</tr>
</tbody>
</table>

| `f.format(u, fc)` | `FC::iterator` | As above, but does not modify `u`. |

#### 22.14.6.3 Formatter specializations [format.formatter.spec]

1 The functions defined in 22.14.5 use specializations of the class template `formatter` to format individual arguments.

2 Let `charT` be either `char` or `wchar_t`. Each specialization of `formatter` is either enabled or disabled, as described below. A debug-enabled specialization of `formatter` additionally provides a public, constexpr, non-static member function `set_debug_format()` which modifies the state of the `formatter` to be as if the type of the `std-format-spec` parsed by the last call to `parse` were ?. Each header that declares the template `formatter` provides the following enabled specializations:

(2.1) The debug-enabled specializations

```cpp
template<> struct formatter<char, char>;
template<> struct formatter<char, wchar_t>;
template<> struct formatter<wchar_t, wchar_t>;
```

(2.2) For each `charT`, the debug-enabled string type specializations

```cpp
template<> struct formatter<basic_string<charT>, charT>;
template<> struct formatter<basic_string_view<charT>, charT>;
template<CharTraits, class Allocator>
    struct formatter<basic_string<CharTraits, Allocator>, charT>;
template<CharTraits>
    struct formatter<basic_string_view<CharTraits>, charT>;
```
For each charT, for each cv-unqualified arithmetic type ArithmeticT other than char, wchar_t, char8_t, char16_t, or char32_t, a specialization

```cpp
template<> struct formatter<ArithmeticT, charT>;
```

For each charT, the pointer type specializations

```cpp
template<> struct formatter<nullptr_t, charT>;
```

```cpp
template<> struct formatter<void*, charT>;
```

```cpp
template<> struct formatter<const void*, charT>;
```

The parse member functions of these formatters interpret the format specification as a std-format-spec as described in 22.14.2.2.

[Note 1: Specializations such as formatter<wchar_t, char> and formatter<const char*, wchar_t> that would require implicit multibyte / wide string or character conversion are disabled. — end note]

For any types T and charT for which neither the library nor the user provides an explicit or partial specialization of the class template formatter<T, charT> is disabled.

3 If the library provides an explicit or partial specialization of formatter<T, charT>, that specialization is enabled and meets the Formatter requirements except as noted otherwise.

If F is a disabled specialization of formatter, these values are false:

1. `is_default_constructible_v<F>`
2. `is_copy_constructible_v<F>`
3. `is_move_constructible_v<F>`
4. `is_copy_assignable_v<F>`
5. `is_move_assignable_v<F>`

An enabled specialization formatter<T, charT> meets the BasicFormatter requirements (22.14.6.1).

[Example 1:
```cpp
#include <format>
#include <string>

enum color { red, green, blue };  
const char* color_names[] = { "red", "green", "blue" };  

template<> struct std::formatter<color> : std::formatter<const char*>
{
  auto format(color c, format_context& ctx) const {
    return formatter<const char*>::format(color_names[c], ctx);
  }
};

type err {};

std::string s0 = std::format("{0}", 42);             // OK, library-provided formatter
std::string s1 = std::format("{0}", L"foo");       // error: disabled formatter
std::string s2 = std::format("{0}", red);          // OK, user-provided formatter
std::string s3 = std::format("{0}", err());        // error: disabled formatter
```

— end example]

### 22.14.6.4 Formatting escaped characters and strings [format.string.escaped]

A character or string can be formatted as escaped to make it more suitable for debugging or for logging.

The escaped string E representation of a string S is constructed by encoding a sequence of characters as follows. The associated character encoding CE for charT (Table 12) is used to both interpret S and construct E.

1. U+0022 QUOTATION MARK (") is appended to E.

2. For each code unit sequence X in S that either encodes a single character, is a shift sequence, or is a sequence of ill-formed code units, processing is in order as follows:

2.1. If X encodes a single character C, then:
— If \( C \) is one of the characters in Table 75, then the two characters shown as the corresponding escape sequence are appended to \( E \).

— Otherwise, if \( C \) is not \( u+0020 \) SPACE and

— \( CE \) is UTF-8, UTF-16, or UTF-32 and \( C \) corresponds to a Unicode scalar value whose Unicode property General_Category has a value in the groups Separator (Z) or Other (\( C \)), as described by UAX #44 of the Unicode Standard, or

— \( CE \) is UTF-8, UTF-16, or UTF-32 and \( C \) corresponds to a Unicode scalar value with the Unicode property Grapheme_Extend=Yes as described by UAX #44 of the Unicode Standard and \( C \) is not immediately preceded in \( S \) by a character \( P \) appended to \( E \) without translation to an escape sequence, or

— \( CE \) is neither UTF-8, UTF-16, nor UTF-32 and \( C \) is one of an implementation-defined set of separator or non-printable characters

then the sequence \( \backslash u\{\text{hex-digit-sequence}\} \) is appended to \( E \), where \text{hex-digit-sequence} is the shortest hexadecimal representation of \( C \) using lower-case hexadecimal digits.

— Otherwise, \( C \) is appended to \( E \).

— Otherwise, if \( X \) is a shift sequence, the effect on \( E \) and further decoding of \( S \) is unspecified.

Recommended practice: A shift sequence should be represented in \( E \) such that the original code unit sequence of \( S \) can be reconstructed.

— Otherwise (\( X \) is a sequence of ill-formed code units), each code unit \( U \) is appended to \( E \) in order as the sequence \( \backslash x\{\text{hex-digit-sequence}\} \), where \text{hex-digit-sequence} is the shortest hexadecimal representation of \( U \) using lower-case hexadecimal digits.

— Finally, \( u+0022 \) QUOTATION MARK (\( " \)) is appended to \( E \).

Table 75 — Mapping of characters to escape sequences

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>U+0009 CHARACTER TABULATION</td>
<td>( \backslash t )</td>
</tr>
<tr>
<td>U+000A LINE FEED</td>
<td>( \backslash n )</td>
</tr>
<tr>
<td>U+000D CARRIAGE RETURN</td>
<td>( \backslash r )</td>
</tr>
<tr>
<td>U+0022 QUOTATION MARK</td>
<td>( &quot; )</td>
</tr>
<tr>
<td>U+005C REVERSE SOLIDUS</td>
<td>( \ )</td>
</tr>
</tbody>
</table>

\( ^3 \) The escaped string representation of a character \( C \) is equivalent to the escaped string representation of a string of \( C \), except that:

— the result starts and ends with \( u+0027 \) APOSTROPHE (\( ' \)) instead of \( u+0022 \) QUOTATION MARK (\( " \)), and

— if \( C \) is \( u+0027 \) APOSTROPHE, the two characters \( \backslash ' \) are appended to \( E \); and

— if \( C \) is \( u+0022 \) QUOTATION MARK, then \( C \) is appended unchanged.

[Example 1:]

```c
string s0 = format("[{}]", "h\tll0");    // s0 has value: [h  \tll0]
string s1 = format("[{?}]", "h\tll0");    // s1 has value: ["h\tll0]
string s2 = format("[{?}]", "Спасибо, Виктор ♥!");      // s2 has value: ["Спасибо, Виктор ♥!"]
string s3 = format("[{?}, {?}]", '\', '''');       // s3 has value: ["'\', '''']
```

// The following examples assume use of the UTF-8 encoding
```c
string s4 = format("[{?}]", string("\0 \n \t \x02 \x1b", 9));    // s4 has value: ["\u{0} \n \t \u{2} \u{1b}"]
string s5 = format("[{?}]", "\xc3\xa8\28");    // invalid UTF-8, s5 has value: ["\x{c3}\"]
string s6 = format("[{?}]", "\c");      // s6 has value: ["\u{0003}\c"]
string s7 = format("[{?}]", "\u0301");      // s7 has value: ["\u{0301}"]
string s8 = format("[{?}]", "\\u0301");      // s8 has value: ["\u{0301}"]
string s9 = format("[{?}]", "\e\u0301\u0323");    // s9 has value: ["\e"]
```

— end example]
`namespace std {`  
`    template<class charT>  
    class basic_format_parse_context {`  
`        public:`  
`            using char_type = charT;  
`            using const_iterator = typename basic_string_view<charT>::const_iterator;  
`            using iterator = const_iterator;  
`        private:`  
`            iterator begin_;  
`            // exposition only  
`            iterator end_;  
`            // exposition only  
`            enum indexing { unknown, manual, automatic };  
`            // exposition only  
`            indexing indexing_;  
`            // exposition only  
`            size_t next_arg_id_;  
`            // exposition only  
`            size_t num_args_;  
`            // exposition only  
`        public:`  
`            constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt) noexcept;`  
`            basic_format_parse_context(const basic_format_parse_context&) = delete;  
`            basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;  
`            constexpr const_iterator begin() const noexcept;  
`            constexpr const_iterator end() const noexcept;  
`            constexpr void advance_to(const_iterator it);  
`            constexpr size_t next_arg_id();  
`            constexpr void check_arg_id(size_t id);  
`            template<class... Ts>`  
`                constexpr void check_dynamic_spec(size_t id) noexcept;`  
`                constexpr void check_dynamic_spec_integral(size_t id) noexcept;  
`                constexpr void check_dynamic_spec_string(size_t id) noexcept;`  
`            };  
`    }`  

1. An instance of `basic_format_parse_context` holds the format string parsing state consisting of the format string range being parsed and the argument counter for automatic indexing.

2. `constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt) noexcept;`  
   
   *Effects*: Initializes `begin_` with `fmt.begin()`, `end_` with `fmt.end()`, `indexing_` with `unknown`, `next_arg_id_` with `0`, and `num_args_` with `0`.  
   
   [Note 1: Any call to `next_arg_id`, `check_arg_id`, or `check_dynamic_spec` on an instance of `basic_format_parse_context` initialized using this constructor is not a core constant expression. — end note]

3. `constexpr const_iterator begin() const noexcept;`  
   
   *Returns*: `begin_`.

4. `constexpr const_iterator end() const noexcept;`  
   
   *Returns*: `end_`.

5. `constexpr void advance_to(const_iterator it);`  
   
   *Preconditions*: `end()` is reachable from `it`.  
   
   *Effects*: Equivalent to: `begin_ = it`;

6. `constexpr size_t next_arg_id();`  
   
   *Effects*: If `indexing_` != `manual` is true, equivalent to:

   ```cpp  
   if (indexing_ == unknown)  
       indexing_ = automatic;  
   return next_arg_id_++;
```
**Throws:** `format_error` if `indexing_ == manual` is `true` which indicates mixing of automatic and manual argument indexing.

**Remarks:** Let `cur-arg-id` be the value of `next_arg_id_` prior to this call. Call expressions where `cur-arg-id >= num_args_` is `true` are not core constant expressions ([7.7]).

```cpp
constexpr void check_arg_id(size_t id);
```

**Effects:** If `indexing_ != automatic` is `true`, equivalent to:

```cpp
if (indexing_ == unknown)
    indexing_ = manual;
```

**Throws:** `format_error` if `indexing_ == automatic` is `true` which indicates mixing of automatic and manual argument indexing.

**Remarks:** Call expressions where `id >= num_args_` is `true` are not core constant expressions ([7.7]).

```cpp
template<class... Ts>
constexpr void check_dynamic_spec(size_t id) noexcept;
```

**Mandates:** The types in `Ts...` are unique. Each type in `Ts...` is one of `bool`, `char_type`, `int`, `unsigned int`, `long long int`, `unsigned long long int`, `float`, `double`, `long double`, `const char_type*`, `basic_string_view<char_type>`, or `const void*`.

**Remarks:** Call expressions where `id >= num_args_` or the type of the corresponding format argument (after conversion to `basic_format_arg<Context>`) is not one of the types in `Ts...` are not core constant expressions ([7.7]).

```cpp
constexpr void check_dynamic_spec_integral(size_t id) noexcept;
```

**Effects:** Equivalent to:

```cpp
check_dynamic_spec<int, unsigned int, long long int, unsigned long long int>(id);
```

```cpp
constexpr void check_dynamic_spec_string(size_t id) noexcept;
```

**Effects:** Equivalent to:

```cpp
check_dynamic_spec<const char_type*, basic_string_view<char_type>>(id);
```

### 22.14.6.6 Class template `basic_format_context`[format.context]

```cpp
namespace std {
    template<class Out, class charT>
    class basic_format_context {
    basic_format_args<basic_format_context> args_;   // exposition only
    Out out_;                                       // exposition only

    public:
        using iterator = Out;
        using char_type = charT;
        template<class T> using formatter_type = formatter<T, charT>;

        basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
        std::locale locale();

        iterator out();
        void advance_to(iterator it);
    };
}
```

1. An instance of `basic_format_context` holds formatting state consisting of the formatting arguments and the output iterator.

2. `Out` shall model `output_iterator<const charT&>`. 

3. `format_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `string`, such as `back_insert_iterator<string>`. Similarly, `wformat_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `wstring`.

4. **Recommended practice:** For a given type `charT`, implementations should provide a single instantiation of `basic_format_context` for appending to `basic_string<charT>`, `vector<charT>`, or any other container.
with contiguous storage by wrapping those in temporary objects with a uniform interface (such as a `span<charT>`) and polymorphic reallocation.

```cpp
basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
```

**Returns:** `args_.get(id)`.

```cpp
std::locale locale();
```

**Returns:** The locale passed to the formatting function if the latter takes one, and `std::locale()` otherwise.

```cpp
iterator out();
```

**Effects:** Equivalent to: `return std::move(out_)`.

```cpp
void advance_to(iterator it);
```

**Effects:** Equivalent to: `out_ = std::move(it);`

**Example 1:**

```cpp
struct S { int value; };
```

```cpp
template<> struct std::formatter<S> {
    size_t width_arg_id = 0;
}
```

```cpp
// Parses a width argument id in the format { digit }.
constexpr auto parse(format_parse_context& ctx) {
    auto iter = ctx.begin();
    auto get_char = [&]() { return iter != ctx.end() ? *iter : 0; }; 
    if (get_char() != '{')
        return iter;
    ++iter;
    char c = get_char();
    if (!isdigit(c) || (++iter, get_char()) != '}
        throw format_error("invalid format");
    width_arg_id = c - '0';
    ctx.check_arg_id(width_arg_id);
    return ++iter;
}
```

```cpp
// Formats an S with width given by the argument width_arg_id.
auto format(S s, format_context& ctx) const {
    int width = ctx.arg(width_arg_id).visit([&](auto value) -> int {
        if constexpr (!is_integral_v<decltype(value)>)
            throw format_error("width is not integral");
        else if (value < 0 || value > numeric_limits<int>::max())
            throw format_error("invalid width");
        else
            return value;
    });
    return format_to(ctx.out(), "{0:x<{1}}", s.value, width);
};
```

```cpp
std::string s = std::format("{0:{1}}", S{42}, 10);  // value of s is "xxxxxxxx42"
```

22.14.7 Formatting of ranges

22.14.7.1 Variable template format_kind

```cpp
template<ranges::input_range R>
requires same_as<R, remove_cvref_t<R>>
constexpr range_format format_kind<R> = see below;
```

A program that instantiates the primary template of `format_kind` is ill-formed.
For a type \( R \), `format_kind<R>` is defined as follows:

\[ (2.1) \]
- If `same_as<remove_cvref_t<ranges::range_reference_t<R>>, R>` is true, `format_kind<R>` is `range_format::disabled`.

[Note 1: This prevents constraint recursion for ranges whose reference type is the same range type. For example, `std::filesystem::path` is a range of `std::filesystem::path`. — end note]

\[ (2.2) \]
- Otherwise, if the qualified-id \( R::key_type \) is valid and denotes a type:
  
  \[ (2.2.1) \]
  - If the qualified-id \( R::mapped_type \) is valid and denotes a type, let \( U \) be `remove_cvref_t<ranges::range_reference_t<R>>`. If either \( U \) is a specialization of `pair` or \( U \) is a specialization of `tuple` and `tuple_size_v<U> == 2`, `format_kind<R>` is `range_format::map`.

\[ (2.2.2) \]
- Otherwise, `format_kind<R>` is `range_format::set`.

\[ (2.3) \]
- Otherwise, `format_kind<R>` is `range_format::sequence`.

**Remarks:** Pursuant to 16.4.5.2.1, users may specialize `format_kind` for cv-unqualified program-defined types that model `ranges::input_range`. Such specializations shall be usable in constant expressions (7.7) and have type `const range_format`.

22.14.7.2 Class template `range_formatter`

```cpp
namespace std {
    template<class T, class charT = char>
    requires same_as<remove_cvref_t<T>, T> && formattable<T, charT>
    class range_formatter {
        formatter<T, charT> underlying_; // exposition only
        basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(" ", " "); // exposition only
        basic_string_view<charT> opening_bracket_ = STATICALLY-WIDEN<charT>("["); // exposition only
        basic_string_view<charT> closing_bracket_ = STATICALLY-WIDEN<charT>("]"); // exposition only

        public:
            constexpr void set_separator(basic_string_view<charT> sep) noexcept;
            constexpr void set_brackets(basic_string_view<charT> opening, basic_string_view<charT> closing) noexcept;
            constexpr formattable<T, charT>& underlying() noexcept { return underlying_; }
            constexpr const formattable<T, charT>& underlying() const noexcept { return underlying_; }

            template<class ParseContext>
            constexpr typename ParseContext::iterator parse(ParseContext& ctx);

            template<ranges::input_range R, class FormatContext>
            requires formattable<ranges::range_reference_t<R>, charT> &&
                same_as<remove_cvref_t<ranges::range_reference_t<R>>, T> &&
                typename FormatContext::iterator format(R&& r, FormatContext& ctx) const;
    }
}
```

1 The class template `range_formatter` is a utility for implementing `formatter` specializations for range types.

2 `range_formatter` interprets `format-spec` as a `range-format-spec`. The syntax of format specifications is as follows:

- `range-format-spec`:
  - `range-fill-and-align_opt width_opt n_opt range-type_opt range-underlying-spec_opt`
  - `range-fill-and-align`
  - `range-fill`
    - any character other than `{ or `}

- `range-type`:
  - `m`
  - `s`
  - `?s`
For `range_formatter<T, charT>`, the `format-spec` in a `range-underlying-spec`, if any, is interpreted by `formatter<T, charT>`.

The `range-fill-and-align` is interpreted the same way as a `fill-and-align` (22.14.2.2). The productions `align` and `width` are described in 22.14.2.

The `n` option causes the range to be formatted without the opening and closing brackets.

[Note 1: This is equivalent to invoking `set_brackets({}, {})`. — end note]

The `range-type` specifier changes the way a range is formatted, with certain options only valid with certain argument types. The meaning of the various type options is as specified in Table 76.

<table>
<thead>
<tr>
<th>Option</th>
<th>Requirements</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>m</code></td>
<td><code>T</code> shall be either a specialization of <code>pair</code> or a specialization of <code>tuple</code> such that <code>tuple_size_v&lt;T&gt;</code> is 2.</td>
<td>Indicates that the opening bracket should be <code>{&quot;, the closing bracket should be &quot;}&quot;, the separator should be &quot;, &quot;, and each range element should be formatted as if </code>m<code>were specified for its</code>tuple-type<code>. [Note 2: If the </code>n<code>option is provided in addition to the</code>m` option, both the opening and closing brackets are still empty. — end note]</td>
</tr>
<tr>
<td><code>s</code></td>
<td><code>T</code> shall be <code>charT</code>.</td>
<td>Indicates that the range should be formatted as a string.</td>
</tr>
<tr>
<td><code>?s</code></td>
<td><code>T</code> shall be <code>charT</code>.</td>
<td>Indicates that the range should be formatted as an escaped string (22.14.6.4).</td>
</tr>
</tbody>
</table>

If the `range-type` is `s` or `?s`, then there shall be no `n` option and no `range-underlying-spec`.

```cpp
csenexpr void set_separator(basic_string_view<charT> sep) noexcept;
```

**Effects:** Equivalent to: `separator_ = sep;`

```cpp
csenexpr void set_brackets(basic_string_view<charT> opening,
                           basic_string_view<charT> closing) noexcept;
```

**Effects:** Equivalent to:

- `opening_bracket_ = opening;`
- `closing_bracket_ = closing;`

```cpp
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

**Effects:** Parses the format specifiers as a `range-format-spec` and stores the parsed specifiers in `*this`. Calls `underlying_.parse(ctx)` to parse `format-spec` in `range-format-spec` or, if the latter is not present, an empty `format-spec`. The values of `opening_bracket_`, `closing_bracket_`, and `separator_` are modified if and only if required by the `range-type` or the `n` option, if present. If:

- the `range-type` is neither `s` nor `?s`,
- `underlying_.set_debug_format()` is a valid expression, and
- there is no `range-underlying-spec`,

then calls `underlying_.set_debug_format()`.

**Returns:** An iterator past the end of the `range-format-spec`.

```cpp
template<ranges::input_range R, class FormatContext>
requires formattable<ranges::range_reference_t<R>, charT> &&
same_as<remove_cvref_t<ranges::range_reference_t<R>>, T>
typename FormatContext::iterator
```

§ 22.14.7.2
11 Effects: Writes the following into ctx.out(), adjusted according to the range-format-spec:

- If the range-type was `s`, then as if by formatting `basic_string<charT>(from_range, r)`.
- Otherwise, if the range-type was `?s`, then as if by formatting `basic_string<charT>(from_range, r)` as an escaped string (22.14.6.4).
- Otherwise,
  - opening-bracket_,
  - for each element `e` of the range `r`:
    - the result of writing `e` via underlying_ and
  - separator_, unless `e` is the last element of `r`, and
  - closing-bracket_.

12 Returns: An iterator past the end of the output range.

### 22.14.7.3 Class template range-default-formatter

```cpp
namespace std {
    template<input_range R, class charT>
    struct range-default-formatter<range_format::sequence, R, charT> {  // exposition only
        private:
            using maybe-const-r = fmt-maybe-const<R, charT>;  // exposition only
            range_formatter<remove_cvref_t<ranges::range_reference_t<maybe-const-r>>, charT> underlying_;  // exposition only
        
        public:
            constexpr void set_separator(basic_string_view<charT> sep) noexcept;
            constexpr void set_brackets(basic_string_view<charT> opening, basic_string_view<charT> closing) noexcept;
            
            template<class ParseContext>
            constexpr typename ParseContext::iterator parse(ParseContext& ctx);
            
            template<class FormatContext>
            typename FormatContext::iterator
            format(maybe-const-r& elems, FormatContext& ctx) const;
        }
    }
}
```

11 Effects: Equivalent to: underlying_.set_separator(sep);

12 Effects: Equivalent to: underlying_.set_brackets(opening, closing);

13 Effects: Equivalent to: return underlying_.parse(ctx);

14 Effects: Equivalent to: return underlying_.format(elems, ctx);

### 22.14.7.4 Specialization of range-default-formatter for maps

```cpp
```
namespace std {
  template<ranges::input_range R, class charT>
  struct range-default-formatter<range_format::map, R, charT> {
    private:
      using maybe-const-map = fmt-maybe-const<R, charT>;
      using element-type =
          remove_cvref_t<ranges::range_reference_t<maybe-const-map>>;
      range_formatter<element-type, charT> underlying_;

    public:
      constexpr range-default-formatter();

      template<class ParseContext>
      constexpr typename ParseContext::iterator parse(ParseContext& ctx);

      template<class FormatContext>
      typename FormatContext::iterator format(maybe-const-map& r, FormatContext& ctx) const;
  };

constexpr range-default-formatter();

1
Mandates: Either:
(1.1) — element-type is a specialization of pair, or
(1.2) — element-type is a specialization of tuple and tuple_size_v<element-type> == 2.

2
Effects: Equivalent to:

underlying_.set_brackets(STATICALLY-WIDEN<charT>("{"), STATICALLY-WIDEN<charT>("}"));
underlying_.underlying().set_brackets({}, {});
underlying_.underlying().set_separator(STATICALLY-WIDEN<charT>(": "));

3
Effects: Equivalent to: return underlying_.parse(ctx);

4
Effects: Equivalent to: return underlying_.format(r, ctx);

22.14.7.5 Specialization of range-default-formatter for sets [format.range.fmtset]

namespace std {
  template<ranges::input_range R, class charT>
  struct range-default-formatter<range_format::set, R, charT> {
    private:
      using maybe-const-set = fmt-maybe-const<R, charT>;
      range_formatter<remove_cvref_t<ranges::range_reference_t<maybe-const-set>>, charT> underlying_;

    public:
      constexpr range-default-formatter();

      template<class ParseContext>
      constexpr typename ParseContext::iterator parse(ParseContext& ctx);

      template<class FormatContext>
      typename FormatContext::iterator format(maybe-const-set & r, FormatContext& ctx) const;
  };

constexpr range-default-formatter();

§ 22.14.7.5
constexpr range-default-formatter();

Effects: Equivalent to:
underlying_.set_brackets(STATICALLY-WIDEN<charT>("{"), STATICALLY-WIDEN<charT>("}"));

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

Effects: Equivalent to: return underlying_.parse(ctx);

template<class FormatContext>
constexpr typename FormatContext::iterator
format(maybe-const-set r, FormatContext& ctx) const;

Effects: Equivalent to: return underlying_.format(r, ctx);

22.14.7.6 Specialization of range-default-formatter for strings

namespace std {

template<range_format K, ranges::input_range R, class charT>
requires (K == range_format::string || K == range_format::debug_string)
struct range-default-formatter<K, R, charT> {
private:
    formatter<basic_string<charT>, charT> underlying_; // exposition only

public:
    template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

    template<class FormatContext>
    constexpr typename FormatContext::iterator
    format(see below r, FormatContext& ctx) const;
};

} // namespace std

1 Mandates: same_as<remove_cvref_t<range_reference_t<R>>, charT> is true.

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

Effects: Equivalent to:
auto i = underlying_.parse(ctx);
if constexpr (K == range_format::debug_string) {
    underlying_.set_debug_format();
}
return i;

template<class FormatContext>
constexpr typename FormatContext::iterator
format(see below r, FormatContext& ctx) const;

The type of r is const R& if ranges::input_range(const R) is true and R& otherwise.

Effects: Let s be a basic_string<charT> such that ranges::equal(s, r) is true. Equivalent to:
return underlying_.format(s, ctx);

22.14.8 Arguments

22.14.8.1 Class template basic_format_arg
namespace std {
    template<class Context>
    class basic_format_arg {
    public:
        class handle;
    private:
        using char_type = typename Context::char_type;
        // exposition only
        variant<monostate, bool, char_type, int, unsigned int, long long int, unsigned long long int,
        float, double, long double, const char_type*, basic_string_view<char_type>,
        const void*, handle> value; // exposition only
        template<class T> explicit basic_format_arg(T& v) noexcept;
    public:
        basic_format_arg() noexcept;
        explicit operator bool() const noexcept;
        template<class Visitor>
        decltype(auto) visit(this basic_format_arg arg, Visitor&& vis);
        template<class R, class Visitor>
        R visit(this basic_format_arg arg, Visitor&& vis);
    }
}

1 An instance of basic_format_arg provides access to a formatting argument for user-defined formatters.
2 The behavior of a program that adds specializations of basic_format_arg is undefined.

    basic_format_arg() noexcept;

    template<class T> explicit basic_format_arg(T& v) noexcept;

    Constraints: T satisfies formattable-with<Context>.

    Preconditions: If decay_t<T> is char_type* or const char_type*, static_cast<const char_type*>(v) points to a NTCTS (3.34).

    Effects: Let TD be remove_const_t<T>.

    (6.1) — If TD is bool or char_type, initializes value with v;
    (6.2) — otherwise, if TD is char and char_type is wchar_t, initializes value with static_cast<wchar_t>(static_cast<unsigned char>(v));
    (6.3) — otherwise, if TD is a signed integer type (6.8.2) and sizeof(TD) <= sizeof(int), initializes value with static_cast<int>(v);
    (6.4) — otherwise, if TD is an unsigned integer type and sizeof(TD) <= sizeof(unsigned int), initializes value with static_cast<unsigned int>(v);
    (6.5) — otherwise, if TD is a signed integer type and sizeof(TD) <= sizeof(long long int), initializes value with static_cast<long long int>(v);
    (6.6) — otherwise, if TD is an unsigned integer type and sizeof(TD) <= sizeof(unsigned long long int), initializes value with static_cast<unsigned long long int>(v);
    (6.7) — otherwise, if TD is a standard floating-point type, initializes value with v;
    (6.8) — otherwise, if TD is a specialization of basic_string_view or basic_string and TD::value_type is char_type, initializes value with basic_string_view<char_type>(v.data(), v.size());
    (6.9) — otherwise, if decay_t<T> is char_type* or const char_type*, initializes value with static_cast<const char_type*>(v);
— otherwise, if is_void_v<remove_pointer_t<TD>> is true or is_null_pointer_v<TD> is true, initializes value with static_cast<const void*>(v);

— otherwise, initializes value with handle(v).

[Note 1: Constructing basic_format_arg from a pointer to a member is ill-formed unless the user provides an enabled specialization of formatter for that pointer to member type. — end note]

explicit operator bool() const noexcept;

Returns: !holds_alternative<monostate>(value).

template<class Visitor>
i

dec(type(auto) visit(this basic_format_arg arg, Visitor& vis);

Effects: Equivalent to: return arg.value.visit(std::forward<Visitor>(vis));

template<class R, class Visitor>
R visit(this basic_format_arg arg, Visitor& vis);

Effects: Equivalent to: return arg.value.visit<R>(std::forward<Visitor>(vis));

The class handle allows formatting an object of a user-defined type.

namespace std {

template<class Context>
class basic_format_arg<Context>::handle {
    const void* ptr_; // exposition only
    void (*format_)(basic_format_parse_context<char_type>&, Context&, const void*); // exposition only

    template<class T> explicit handle(T& val) noexcept; // exposition only

    friend class basic_format_arg<Context>; // exposition only

    public:
        void format(basic_format_parse_context<char_type>&, Context& ctx) const;
    };

    template<class T> explicit handle(T& val) noexcept;

Let

— TD be remove_const_t<T>,

— TQ be const TD if const TD satisfies formattable-with<Context> and TD otherwise.

Mandates: TQ satisfies formattable-with<Context>.

Effects: Initializes ptr_ with addressof(val) and format_ with

[](basic_format_parse_context<char_type>& parse_ctx,
    Context& format_ctx, const void* ptr) {
    typename Context::template formatter_type<TD> f;
    parse_ctx.advance_to(f.parse(parse_ctx));
    format_ctx.advance_to(f.format(*const_cast<TQ*>(static_cast<const TD*>(ptr)),
        format_ctx));
}

void format(basic_format_parse_context<char_type>& parse_ctx, Context& format_ctx) const;

Effects: Equivalent to: format_(parse_ctx, format_ctx, ptr_);

22.14.8.2 Class template format-arg-store

namespace std {

template<class Context, class... Args>
class format-arg-store {
    // exposition only
    array<basic_format_arg<Context>, sizeof...(Args)> args; // exposition only
};
}

§ 22.14.8.2
An instance of `format-arg-store` stores formatting arguments.

```cpp
template<class Context = format_context, class... Args>
    format-arg-store<Context, Args...> make_format_args(Args&... fmt_args);
```

Preconditions: The type `typename Context::template formatter_type<remove_const_t<T>>` meets the BasicFormatter requirements (22.14.6.1) for each `T` in `Args`.

Returns: An object of type `format-arg-store<Context, Args...>` whose `args` data member is initialized with `{basic_format_arg<Context>(fmt_args)...}`.

```cpp
template<class... Args>
    format-arg-store<wformat_context, Args...> make_wformat_args(Args&... args);
```

Effects: Equivalent to: `return make_format_args<wformat_context>(args...);`

### 22.14.8.3 Class template `basic_format_args`

```cpp
namespace std {
    template<class Context>
        class basic_format_args {
            size_t size_; // exposition only
            const basic_format_arg<Context>* data_; // exposition only

    public:
        basic_format_args() noexcept;
        template<class... Args>
            basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

        basic_format_arg<Context> get(size_t i) const noexcept;
    }
}
```

An instance of `basic_format_args` provides access to formatting arguments. Implementations should optimize the representation of `basic_format_args` for a small number of formatting arguments.

[Note 1: For example, by storing indices of type alternatives separately from values and packing the former. — end note]

1. `basic_format_args()` noexcept;

   Effects: Initializes `size_` with 0.

2. `template<class... Args>
    basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

   Effects: Initializes `size_` with `sizeof...(Args)` and `data_` with `store.args.data()`.

3. `basic_format_arg<Context> get(size_t i) const noexcept;

### 22.14.9 Tuple formatter

For each of `pair` and `tuple`, the library provides the following formatter specialization where `pair-or-tuple` is the name of the template:

```cpp
namespace std {
    template<class charT, formattable<charT>... Ts>
        struct formatter<pair-or-tuple<Ts...>, charT> {
            private:
                tuple<formatter<remove_cvref_t<Ts>>, charT>... underlying_; // exposition only
                basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(" ", ""); // exposition only
                basic_string_view<charT> opening_bracket_ = STATICALLY-WIDEN<charT>("("); // exposition only
                basic_string_view<charT> closing_bracket_ = STATICALLY-WIDEN<charT>(")"); // exposition only
        }
}
```

§ 22.14.9 840
public:
constexpr void set_separator(basic_string_view<charT> sep) noexcept;
constexpr void set_brackets(basic_string_view<charT> opening,
    basic_string_view<charT> closing) noexcept;

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

template<class FormatContext>
typename FormatContext::iterator
format(see below elems, FormatContext& ctx) const;

2 The `parse` member functions of these formatters interpret the format specification as a `tuple-format-spec` according to the following syntax:

```
tuple-format-spec:
tuple-fill-and-align_opt width_opt tuple-type_opt
```

- `tuple-fill-and-align`:
  - `tuple-fill`: any character other than { or } or :
  - `tuple-type`:
    - `m`: sizeof...(Ts) == 2
    - `n`: none

3 The `tuple-fill-and-align` is interpreted the same way as a `fill-and-align` (22.14.2.2). The productions `align` and `width` are described in 22.14.2.

4 The `tuple-type` specifier changes the way a `pair` or `tuple` is formatted, with certain options only valid with certain argument types. The meaning of the various type options is as specified in Table 77.

Table 77 — Meaning of `tuple-type` options  
[tab:formatter.tuple.type]

<table>
<thead>
<tr>
<th>Option</th>
<th>Requirements</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>sizeof...(Ts) == 2</td>
<td>Equivalent to: set_separator(STATICALLY-WIDEN&lt;charT&gt;(&quot; : &quot;)); set_brackets({}, {});</td>
</tr>
<tr>
<td>n</td>
<td>none</td>
<td>Equivalent to: set_brackets({}, {});</td>
</tr>
<tr>
<td>none</td>
<td>none</td>
<td>No effects</td>
</tr>
</tbody>
</table>

5 \textit{Effects}: Equivalent to: `separator_ = sep;`

6 \textit{Effects}: Equivalent to:

```
    opening-bracket_ = opening;
    closing-bracket_ = closing;
```

7 \textit{Effects}: Parses the format specifiers as a `tuple-format-spec` and stores the parsed specifiers in `*this`. The values of `opening-bracket_`, `closing-bracket_`, and `separator_` are modified if and only if required by the `tuple-type`, if present. For each element `e` in `underlying_`, calls `e.parse(ctx)` to parse an empty `format-spec` and, if `e.set_debug_format()` is a valid expression, calls `e.set_debug_format()`.
template<class FormatContext>
typename FormatContext::iterator
    format(see below& elems, FormatContext& ctx) const;

The type of elems is:
1. If (formattable<const Ts, charT> && ...) is true, const pair-or-tuple<Ts...>&.
2. Otherwise pair-or-tuple<Ts...>&.

Effects: Writes the following into ctx.out(), adjusted according to the tuple-format-spec:
1. opening-bracket_,
2. for each index I in the [0, sizeof...(Ts)):
   1. if I != 0, separator_,
   2. the result of writing get<I>(elems) via get<I>(underlying_), and
3. closing-bracket_.

Returns: An iterator past the end of the output range.

22.14.10 Class format_error

namespace std {
    class format_error : public runtime_error {
    public:
        explicit format_error(const string& what_arg);
        explicit format_error(const char* what_arg);
    }
}

The class format_error defines the type of objects thrown as exceptions to report errors from the formatting library.

format_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

format_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

22.15 Bit manipulation

22.15.1 General

The header <bit> provides components to access, manipulate and process both individual bits and bit sequences.

22.15.2 Header <bit> synopsis

// all freestanding
namespace std {
    // 22.15.3, bit_cast
    template<class To, class From>
    constexpr To bit_cast(const From& from) noexcept;

    // 22.15.4, byteswap
    template<class T>
    constexpr T byteswap(T value) noexcept;

    // 22.15.5, integral powers of 2
    template<class T>
    constexpr bool has_single_bit(T x) noexcept;
    template<class T>
    constexpr T bit_ceil(T x);
    template<class T>
    constexpr T bit_floor(T x);
    template<class T>
    constexpr T bit_floor(T x) noexcept;

§ 22.15.2
template<class T>
constexpr int bit_width(T x) noexcept;

// 22.15.6, rotating
template<class T>
[[nodiscard]] constexpr T rotl(T x, int s) noexcept;
template<class T>
[[nodiscard]] constexpr T rotr(T x, int s) noexcept;

// 22.15.7, counting
template<class T>
constexpr int countl_zero(T x) noexcept;
template<class T>
constexpr int countl_one(T x) noexcept;
template<class T>
constexpr int countr_zero(T x) noexcept;
template<class T>
constexpr int countr_one(T x) noexcept;
template<class T>
constexpr int popcount(T x) noexcept;

// 22.15.8, endian
enum class endian {
  little = see below,
  big = see below,
  native = see below
};

22.15.3 Function template bit_cast

template<class To, class From>
constexpr To bit_cast(const From& from) noexcept;

1
(1.1) sizeof(To) == sizeof(From) is true;
(1.2) is_trivially_copyable_v<To> is true; and
(1.3) is_trivially_copyable_v<From> is true.

2
Returns: An object of type To. Implicitly creates objects nested within the result (6.7.2). Each bit of the value representation of the result is equal to the corresponding bit in the object representation of from. Padding bits of the result are unspecified. For the result and each object created within it, if there is no value of the object’s type corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified. A bit in the value representation of the result is indeterminate if it does not correspond to a bit in the value representation of from or corresponds to a bit of an object that is not within its lifetime or has an indeterminate value (6.7.4). For each bit in the value representation of the result that is indeterminate, the smallest object containing that bit has an indeterminate value; the behavior is undefined unless that object is of unsigned ordinary character type or std::byte type. The result does not otherwise contain any indeterminate values.

3
Remarks: This function is constexpr if and only if To, From, and the types of all subobjects of To and From are types T such that:
(3.1) is_union_v<T> is false;
(3.2) is_pointer_v<T> is false;
(3.3) is_member_pointer_v<T> is false;
(3.4) is_volatile_v<T> is false; and
(3.5) T has no non-static data members of reference type.
22.15.4 byteswap

```cpp
template<class T>
constexpr T byteswap(T value) noexcept;
```

- **Constraints:** T models integral.
- **Mandates:** T does not have padding bits (6.8.1).
- **Let the sequence R comprise the bytes of the object representation of value in reverse order.**
- **Returns:** An object v of type T such that each byte in the object representation of v is equal to the byte in the corresponding position in R.

22.15.5 Integral powers of 2

```cpp
template<class T>
constexpr bool has_single_bit(T x) noexcept;
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Returns:** true if x is an integral power of two; false otherwise.

```cpp
template<class T>
constexpr T bit_ceil(T x);
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Preconditions:** N is representable as a value of type T.
- **Returns:** N.
- **Throws:** Nothing.
- **Remarks:** A function call expression that violates the precondition in the Preconditions: element is not a core constant expression (7.7).

```cpp
template<class T>
constexpr T bit_floor(T x) noexcept;
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Returns:** If x == 0, 0; otherwise the maximal value y such that has_single_bit(y) is true and y <= x.

```cpp
template<class T>
constexpr int bit_width(T x) noexcept;
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Returns:** If x == 0, 0; otherwise one plus the base-2 logarithm of x, with any fractional part discarded.

22.15.6 Rotating

In the following descriptions, let N denote numeric_limits<T>::digits.

```cpp
template<class T>
[[nodiscard]] constexpr T rotl(T x, int s) noexcept;
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Let r be s % N.**
- **Returns:** If r is 0, x; if r is positive, (x << r) | (x >> (N - r)); if r is negative, rotr(x, -r).

```cpp
template<class T>
[[nodiscard]] constexpr T rotr(T x, int s) noexcept;
```

- **Constraints:** T is an unsigned integer type (6.8.2).
- **Let r be s % N.**
- **Returns:** If r is 0, x; if r is positive, (x >> r) | (x << (N - r)); if r is negative, rotl(x, -r).
22.15.7 Counting [bit.count]

In the following descriptions, let \( N \) denote `numeric_limits<T>::digits`.

```cpp
template<class T>
constexpr int countl_zero(T x) noexcept;
```

2

**Constraints:** \( T \) is an unsigned integer type (6.8.2).

3

**Returns:** The number of consecutive 0 bits in the value of \( x \), starting from the most significant bit.

[Note 1: Returns \( N \) if \( x == 0 \). — end note]

```cpp
template<class T>
constexpr int countl_one(T x) noexcept;
```

4

**Constraints:** \( T \) is an unsigned integer type (6.8.2).

5

**Returns:** The number of consecutive 1 bits in the value of \( x \), starting from the most significant bit.

[Note 2: Returns \( N \) if \( x == numeric_limits<T>::max() \). — end note]

```cpp
template<class T>
constexpr int countr_zero(T x) noexcept;
```

6

**Constraints:** \( T \) is an unsigned integer type (6.8.2).

7

**Returns:** The number of consecutive 0 bits in the value of \( x \), starting from the least significant bit.

[Note 3: Returns \( N \) if \( x == 0 \). — end note]

```cpp
template<class T>
constexpr int countr_one(T x) noexcept;
```

8

**Constraints:** \( T \) is an unsigned integer type (6.8.2).

9

**Returns:** The number of consecutive 1 bits in the value of \( x \), starting from the least significant bit.

[Note 4: Returns \( N \) if \( x == numeric_limits<T>::max() \). — end note]

```cpp
template<class T>
constexpr int popcount(T x) noexcept;
```

10

**Constraints:** \( T \) is an unsigned integer type (6.8.2).

11

**Returns:** The number of 1 bits in the value of \( x \).

22.15.8 Endian [bit.endian]

Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```cpp
enum class endian {
    little = see below,
    big = see below,
    native = see below
};
```

12

If all scalar types have size 1 byte, then all of `endian::little`, `endian::big`, and `endian::native` have the same value. Otherwise, `endian::little` is not equal to `endian::big`. If all scalar types are big-endian, `endian::native` is equal to `endian::big`. If all scalar types are little-endian, `endian::native` is equal to `endian::little`. Otherwise, `endian::native` is not equal to either `endian::big` or `endian::little`.

22.16 Debugging [debugging]

22.16.1 General [debugging.general]

Subclause 22.16 describes functionality to introspect and interact with the execution of the program.

[Note 1: The facilities provided by the debugging functionality interact with a program that could be tracing the execution of a C++ program, such as a debugger. — end note]
22.16.2 Header <debugging> synopsis

// all freestanding
namespace std {
    // 22.16.3, utility
    void breakpoint() noexcept;
    void breakpoint_if_debugging() noexcept;
    bool is_debugger_present() noexcept;
}

22.16.3 Utility

void breakpoint() noexcept;

1 The semantics of this function are implementation-defined.

[Note 1: When invoked, the execution of the program temporarily halts and execution is handed to the debugger until such a time as: The program is terminated by the debugger, or the debugger resumes execution of the program as if the function was not invoked. — end note]

void breakpoint_if_debugging() noexcept;

2 Effects: Equivalent to:

    if (is_debugger_present()) breakpoint();

bool is_debugger_present() noexcept;

3 The semantics of this function are implementation-defined.

[Note 2: When tracing the execution of a program with a debugger, an implementation returns true. An implementation performs an immediate query, as needed, to determine if the program is traced by a debugger. On Windows or equivalent systems, this can be achieved by calling the ::IsDebuggerPresent() Win32 function. On POSIX, this can be achieved by checking for a tracer parent process, with best effort determination that such a tracer parent process is a debugger. — end note]
23 Strings library [strings]

23.1 General [strings.general]
1 This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.8.1) type. Such types are called char-like types, and objects of char-like types are called char-like objects or simply characters.
2 The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 78.

Table 78 — Strings library summary [tab:strings.summary]

</tr>
</tbody>
</table>

23.2 Character traits [char.traits]

23.2.1 General [char.traits.general]
1 Subclause 23.2 defines requirements on classes representing character traits, and defines a class template char_traits<charT>, along with five specializations, char_traits<char>, char_traits<char8_t>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>, that meet those requirements.
2 Most classes specified in 23.4, 23.3, and Clause 31 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by each such template. Subclause 23.2 defines the semantics of these members.
3 To specialize those templates to generate a string, string view, or iostream class to handle a particular character container type (3.10) C, that and its related character traits class X are passed as a pair of parameters to the string, string view, or iostream template as parameters charT and traits. If X::char_type is not the same type as C, the program is ill-formed.

23.2.2 Character traits requirements [char.traits.require]
1 In Table 79, X denotes a traits class defining types and functions for the character container type C; c and d denote values of type C; p and q denote values of type const C*; s denotes a value of type C*; n, i and j denote values of type size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; and r denotes an lvalue of type C. No expression which is part of the character traits requirements specified in this subclause 23.2.2 shall exit via an exception.

<td>constant</td>
<td>X::eof()</td>
</tr>
</tbody>
</table>

2 The class template

```cpp
template<class charT> struct char_traits;
```

is provided in the header `<string>` as a basis for explicit specializations.

### 23.2.3 Traits typedefs

```cpp
using int_type = see below;
```

1. **Preconditions:** `int_type` shall be able to represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`.

```cpp
using state_type = see below;
```

2. **Preconditions:** `state_type` meets the `Cpp17Destructible` (Table 35), `Cpp17CopyAssignable` (Table 34), `Cpp17CopyConstructible` (Table 32), and `Cpp17DefaultConstructible` (Table 30) requirements.

### 23.2.4 char_traits specializations

### 23.2.4.1 General

```cpp
namespace std {
  template<> struct char_traits<char> {
    using char_type = char;
    using int_type = int;
    using off_type = streamoff;
    using pos_type = streampos;
    using state_type = mbstate_t;
    using comparison_category = strong_ordering;

    static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;
  }
}
```

1. The header `<string>` defines five specializations of the class template `char_traits`: `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`.

### 23.2.4.2 struct char_traits<char>

```cpp
namespace std {
  template<> struct char_traits<char> {
    using char_type = char;
    using int_type = int;
    using off_type = streamoff;
    using pos_type = streampos;
    using state_type = mbstate_t;
    using comparison_category = strong_ordering;

    static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;
    ...
  }
}
```

---

204) If `eof()` can be held in `char_type` then some iostreams operations can give surprising results.
static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
static constexpr bool eq(char_type c1, char_type c2) noexcept;
static constexpr bool lt(char_type c1, char_type c2) noexcept;
static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;

};

1 The type mbstate_t is defined in <cwchar> and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

2 The two-argument member assign is defined identically to the built-in operator =. The two-argument members eq and lt are defined identically to the built-in operators == and < for type unsigned char.

3 The member eof() returns EOF.

23.2.4.3 struct char_traits<char8_t> [char.traits.specializations.char8.t]

namespace std {
    template<> struct char_traits<char8_t> {
        using char_type = char8_t;
        using int_type = unsigned int;
        using off_type = streamoff;
        using pos_type = u8streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };

    static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;
    static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
    static constexpr size_t length(const char_type* s);
    static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
    static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
    static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static constexpr char_type* assign(char_type* s, size_t n, char_type a);
    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;

};

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and < respectively.

2 The member eof() returns an implementation-defined constant that cannot appear as a valid UTF-8 code unit.

23.2.4.4 struct char_traits<char16_t> [char.traits.specializations.char16.t]

namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;

    };
using state_type = mbstate_t;
using comparison_category = strong_ordering;

static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
static constexpr bool eq(char_type c1, char_type c2) noexcept;
static constexpr bool lt(char_type c1, char_type c2) noexcept;
static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n,
                        const char_type& a);
static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;

};

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

23.2.4.5 struct char_traits<char32_t> [char.traits.specializations.char32.t]

namespace std {

template<> struct char_traits<char32_t> {  
    using char_type = char32_t;
    using int_type = uint_least32_t;
    using off_type = streamoff;
    using pos_type = u32streampos;
    using state_type = mbstate_t;
    using comparison_category = strong_ordering;

    static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
    static constexpr bool eq(char_type c1, char_type c2) noexcept;
    static constexpr bool lt(char_type c1, char_type c2) noexcept;
    static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
    static constexpr size_t length(const char_type* s);
    static constexpr const char_type* find(const char_type* s, size_t n,
                                              const char_type& a);
    static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
    static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
    static constexpr char_type* assign(char_type* s, size_t n, char_type a);
    static constexpr int_type not_eof(int_type c) noexcept;
    static constexpr char_type to_char_type(int_type c) noexcept;
    static constexpr int_type to_int_type(char_type c) noexcept;
    static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    static constexpr int_type eof() noexcept;
};

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns an implementation-defined constant that cannot appear as a Unicode code point.
23.2.4.6 struct char_traits<wchar_t> [char.traits.specializations.wchar.t]

namespace std {
    template<> struct char_traits<wchar_t> {
        using char_type    = wchar_t;
        using int_type     = wint_t;
        using off_type     = streamoff;
        using pos_type     = wstreampos;
        using state_type   = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                                const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns WEOF.

23.3 String view classes [string.view]

23.3.1 General [string.view.general]

1 The class template basic_string_view describes an object that can refer to a constant contiguous sequence of char-like (23.1) objects with the first element of the sequence at position zero. In the rest of 23.3, the type of the char-like objects held in a basic_string_view object is designated by charT.

2 [Note 1: The library provides implicit conversions from const charT* and std::basic_string<charT, ...> to std::basic_string_view<charT, ...> so that user code can accept just std::basic_string_view<charT> as a non-templated parameter wherever a sequence of characters is expected. User-defined types can define their own implicit conversions to std::basic_string_view<charT> in order to interoperate with these functions. — end note]

23.3.2 Header <string_view> synopsis [string.view.synop]

// mostly freestanding

}
}

The function templates defined in 22.2.2 and 25.7 are available when <string_view> is included.

23.3.3 Class template basic_string_view

23.3.3.1 General

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view {
        public:
            // types
            using traits_type = traits;
            using value_type = charT;
            using pointer = value_type*;
            using const_pointer = const value_type*;
            using reference = value_type&;
            using const_reference = const value_type&;
            using const_iterator = implementation-defined;  // see 23.3.3.4
            using iterator = const_iterator;
            using const_reverse_iterator = reverse_iterator<const_iterator>;
            using reverse_iterator = const_reverse_iterator;
            using size_type = size_t;
            using difference_type = ptrdiff_t;
            static constexpr size_type npos = size_type(-1);

        205) Because basic_string_view refers to a constant sequence, iterator and const_iterator are the same type.
// 23.3.3.2, construction and assignment
constexpr basic_string_view() noexcept;

constexpr size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
    const_pointer data_;     // exposition only
    size_type size_;         // exposition only
};

// 23.3.3.3, deduction guides
template<class It, class End>
    basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;
template<class R>
    basic_string_view(R&&) -> basic_string_view<ranges::range_value_t<R>>;

1 In every specialization basic_string_view<charT, traits>, the type traits shall meet the character traits requirements (23.2).

[Note 1: The program is ill-formed if traits::char_type is not the same type as charT. — end note]

2 For a basic_string_view str, any operation that invalidates a pointer in the range
[.str.data(), .str.data() + .str.size())
invalidates pointers, iterators, and references to elements of str.

3 The complexity of basic_string_view member functions is $O(1)$ unless otherwise specified.

4 basic_string_view<charT, traits> is a trivially copyable type (6.8.1).

23.3.3.2 Construction and assignment

constexpr basic_string_view() noexcept;

Postconditions: size_ == 0 and data_ == nullptr.
constexpr basic_string_view(const charT* str);

Preconditions: \([str, str + traits::length(str))\) is a valid range.

Effects: Constructs a basic_string_view, initializing data_ with str and initializing size_ with traits::length(str).

Complexity: \(O(\text{traits::length(str)})\).

constexpr basic_string_view(const charT* str, size_type len);

Preconditions: \([str, str + \text{len})\) is a valid range.

Effects: Constructs a basic_string_view, initializing data_ with str and initializing size_ with len.

template<class It, class End>
constexpr basic_string_view(It begin, End end);

Constraints:

(7.1) It satisfies contiguous_iterator.
(7.2) End satisfies sized_sentinel_for<It>.
(7.3) is_same_v<iter_value_t<It>, charT> is true.
(7.4) is_convertible_v<End, size_type> is false.

Preconditions:

(8.1) \([\text{begin}, \text{end})\) is a valid range.
(8.2) It models contiguous_iterator.
(8.3) End models sized_sentinel_for<It>.

Effects: Initializes data_ with \(\text{to_address}(<\text{begin})\) and initializes size_ with \(\text{end} - \text{begin}\).

Throws: When and what \(\text{end} - \text{begin}\) throws.

template<class R>
constexpr explicit basic_string_view(R&& r);

Let \(d\) be an lvalue of type remove_cvref_t<R>.

Constraints:

(12.1) remove_cvref_t<R> is not the same type as basic_string_view,
(12.2) R models ranges::contiguous_range and ranges::sized_range,
(12.3) is_same_v<ranges::range_value_t<\text{R}>, charT> is true,
(12.4) is_convertible_v<\text{R}, const charT*> is false, and
(12.5) \(\text{d}.\text{operator ::std::basic_string_view<charT, traits}>()\) is not a valid expression.

Effects: Initializes data_ with ranges::data<\text{r}) and size_ with ranges::size<\text{r}).

Throws: Any exception thrown by ranges::data<\text{r}) and ranges::size<\text{r}>>.

23.3.3.3 Deduction guides

template<class It, class End>
basic_string_view(It, End) \to basic_string_view<iter_value_t<It>>;

Constraints:

(1.1) It satisfies contiguous_iterator.
(1.2) End satisfies sized_sentinel_for<It>.

template<class R>
basic_string_view(R&&) \to basic_string_view<ranges::range_value_t<\text{R}>>;

Constraints: R satisfies ranges::contiguous_range.

23.3.3.4 Iterator support
using const_iterator = implementation-defined;

A type that meets the requirements of a constant Cpp17RandomAccessIterator (25.3.5.7), models contiguous_iterator (25.3.4.14), and meets the constexpr iterator requirements (25.3.1), whose value_type is the template parameter charT.

All requirements on container iterators (24.2) apply to basic_string_view::const_iterator as well.

constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator such that

— if !empty(), addressof(*begin()) == data_,
— otherwise, an unspecified value such that [begin(), end()) is a valid range.

constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: begin() + size().

constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: const_reverse_iterator(end()).

constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: const_reverse_iterator(begin()).

23.3.3.5 Capacity

constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;

Returns: size_.

constexpr size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be referred to by a basic_string_view.

[[nodiscard]] constexpr bool empty() const noexcept;

Returns: size_ == 0.

23.3.3.6 Element access

constexpr const_reference operator[](size_type pos) const;

Preconditions: pos < size().

Returns: data_[pos].

Throws: Nothing.

[Note 1: Unlike basic_string::operator[], basic_string_view::operator[](size()) has undefined behavior instead of returning charT(). — end note]

constexpr const_reference at(size_type pos) const;

Returns: data_[pos].

Throws: out_of_range if pos >= size().

constexpr const_reference front() const;

Preconditions: !empty().

Returns: data_[0].

Throws: Nothing.
```plaintext
constexpr const_reference back() const;
   
   Preconditions: !empty().

   Returns: data_[size() - 1].

   Throws: Nothing.

constexpr const_pointer data() const noexcept;

   Returns: data_.

   [Note 2: Unlike basic_string::data() and string-literals, data() can return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass data() to a function that takes just a const charT* and expects a null-terminated string. —end note]

23.3.3.7 Modifiers

constexpr void remove_prefix(size_type n);
   
   Preconditions: n <= size().

   Effects: Equivalent to: data_ += n; size_ -= n;

constexpr void remove_suffix(size_type n);

   Preconditions: n <= size().

   Effects: Equivalent to: size_ -= n;

constexpr void swap(basic_string_view& s) noexcept;

   Effects: Exchanges the values of *this and s.

23.3.3.8 String operations

constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;

   Let rlen be the smaller of n and size() - pos.

   Preconditions: [s, s + rlen) is a valid range.

   Effects: Equivalent to traits::copy(s, data() + pos, rlen).

   Returns: rlen.

   Throws: out_of_range if pos > size().

   Complexity: \( \mathcal{O}(rlen) \).

constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;

   Let rlen be the smaller of n and size() - pos.

   Effects: Determines rlen, the effective length of the string to reference.

   Returns: basic_string_view(data() + pos, rlen).

   Throws: out_of_range if pos > size().

constexpr int compare(basic_string_view str) const noexcept;

   Let rlen be the smaller of size() and str.size().

   Effects: Determines rlen, the effective length of the strings to compare. The function then compares the two strings by calling traits::compare(data(), str.data(), rlen).

   Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 80.

   Table 80 — compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>

\begin{verbatim}
constexpr bool contains(basic_string_view x) const noexcept;
\end{verbatim}
\begin{verbatim}
constexpr bool contains(charT x) const noexcept;
\end{verbatim}
\begin{verbatim}
constexpr bool contains(const charT* x) const;
\end{verbatim}

\textit{Effects:} Equivalent to: find(x) != npos;

\subsection*{23.3.3.9 Searching \[string.view.find\]}

1 Member functions in this subclause have complexity \mathcal{O}(size() * \text{str.size()}) at worst, although implementations should do better.

2 Let \(F\) be one of \textit{find}, \textit{rfind}, \textit{find_first_of}, \textit{find_last_of}, \textit{find_first_not_of}, and \textit{find_last_not_of}.

\begin{enumerate}
\item Each member function of the form
\begin{verbatim}
constexpr return-type F(const charT* s, size_type pos) const;
\end{verbatim}
has effects equivalent to: return \(F(\text{basic_string_view(s)}, \text{pos})\);  
\item Each member function of the form
\begin{verbatim}
constexpr return-type F(const charT* s, size_type pos, size_type n) const;
\end{verbatim}
has effects equivalent to: return \(F(\text{basic_string_view(s, n)}, \text{pos})\);  
\item Each member function of the form
\end{enumerate}
constexpr return-type F(charT c, size_type pos) const noexcept;
has effects equivalent to: return F(basic_string_view(addressof(c), 1), pos);

constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;
Let xpos be the lowest position, if possible, such that the following conditions hold:
  — pos <= xpos
  — pos + str.size() <= size()
  — traits::eq(data_[xpos + I], str[I]) for all elements I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type rfind(basic_string_view str, size_type pos = npos) const noexcept;
Let xpos be the highest position, if possible, such that the following conditions hold:
  — xpos <= pos
  — xpos + str.size() <= size()
  — traits::eq(data_[xpos + I], str[I]) for all elements I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_first_of(basic_string_view str, size_type pos = 0) const noexcept;
Let xpos be the lowest position, if possible, such that the following conditions hold:
  — pos <= xpos
  — pos < size()
  — traits::eq(data_[xpos], str[I]) for some element I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_last_of(basic_string_view str, size_type pos = npos) const noexcept;
Let xpos be the highest position, if possible, such that the following conditions hold:
  — xpos <= pos
  — xpos < size()
  — traits::eq(data_[xpos], str[I]) for some element I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_first_not_of(basic_string_view str, size_type pos = 0) const noexcept;
Let xpos be the lowest position, if possible, such that the following conditions hold:
  — pos <= xpos
  — pos < size()
  — traits::eq(data_[xpos], str[I]) for no element I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

constexpr size_type find_last_not_of(basic_string_view str, size_type pos = npos) const noexcept;
Let xpos be the highest position, if possible, such that the following conditions hold:
  — xpos <= pos
  — xpos < size()
  — traits::eq(data_[xpos], str[I]) for no element I of the string referenced by str.
Effects: Determines xpos.
Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.
**Effects**: Determines \( \text{xpos} \).

**Returns**: \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

### 23.3.4 Non-member comparison functions

Let \( S \) be \texttt{basic\_string\_view<\texttt{charT}, \texttt{traits}>}, and \( sv \) be an instance of \( S \). Implementations shall provide sufficient additional overloads marked \texttt{constexpr} and \texttt{noexcept} so that an object \( t \) with an implicit conversion to \( S \) can be compared according to Table 81.

**Table 81** — Additional \texttt{basic\_string\_view} comparison overloads

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>

</tbody>
</table>

[Example 1: A sample conforming implementation for \texttt{operator==} would be:

```cpp
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}

template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
type_identity_t<basic_string_view<charT, traits>> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
```

— end example]

**Returns**: \( \text{lhs.compare(rhs)} == 0 \).

**Mandates**: \( R \) denotes a comparison category type (17.11.2).

**Returns**: \( \text{static\_cast}<R>(\text{lhs.compare(rhs)} <= 0) \).
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);

Effects: Behaves as a formatted output function (31.7.6.3.1) of os. Forms a character sequence seq,
initially consisting of the elements defined by the range [str.begin(), str.end()). Determines padding
for seq as described in 31.7.6.3.1. Then inserts seq as if by calling os.rdbuf()->sputn(seq, n),
where n is the larger of os.width() and str.size(); then calls os.width(0).

Returns: os

23.3.6 Hash support

template<> struct hash<string_view>;
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

The specialization is enabled (22.10.19).

[Note 1: The hash value of a string view object is equal to the hash value of the corresponding string
object (23.4.6). — end note]

23.3.7 Suffix for basic_string_view literals

constexpr string_view operator"sv(const char* str, size_t len) noexcept;

Returns: string_view{str, len}.

constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept;

Returns: u8string_view{str, len}.

constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;

Returns: u16string_view{str, len}.

constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;

Returns: u32string_view{str, len}.

constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;

Returns: wstring_view{str, len}.

23.4 String classes

23.4.1 General

The header <string> defines the basic_string class template for manipulating varying-length sequences
of char-like objects and five typedef-names, string, u8string, u16string, u32string, and wstring,
that name the specializations basic_string<char>, basic_string<char8_t>, basic_string<char16_t>,
basic_string<char32_t>, and basic_string<wchar_t>, respectively.

23.4.2 Header <string> synopsis

#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2

23.4.3 Class template basic_string [basic.string]
23.4.3.1 General [basic.string.general]
1 The class template basic_string describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also
```
called a “string” if the type of the char-like objects that it holds is clear from context. In the rest of 23.4.3, the type of the char-like objects held in a basic_string object is designated by charT.

2 A specialization of basic_string is a contiguous container (24.2.2.2).

3 In all cases, [data(), data() + size()] is a valid range, data() + size() points at an object with value charT() (a “null terminator”), and size() <= capacity() is true.

namespace std {
  template<class charT, class traits = char_traits<charT>,
  class Allocator = allocator<charT>>
  class basic_string {
    public:
      // types
      using traits_type = traits;
      using value_type = charT;
      using allocator_type = Allocator;
      using size_type = typename allocator_traits<Allocator>::size_type;

const expr bool contains(const charT* x) const;

};

template<class InputIterator,
  class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
basic_string(InputIterator, InputIterator, Allocator = Allocator())
-> basic_string<typename iterator_traits<InputIterator>::value_type,
  char_traits<typename iterator_traits<InputIterator>::value_type>,
  Allocator>;

template<ranges::input_range R,
  class Allocator = allocator<ranges::range_value_t<R>>>
basic_string(from_range_t, R&&, Allocator = Allocator())
-> basic_string<ranges::range_value_t<R>, char_traits<ranges::range_value_t<R>>,
  Allocator>;

template<class charT,
  class traits,
  class Allocator = allocator<charT>>
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;

template<class charT,
  class traits,
  class Allocator = allocator<charT>>
basic_string(basic_string_view<charT, traits>,
  typename see below::size_type, typename see below::size_type,
  const Allocator& = Allocator())
A \texttt{size\_type} parameter type in a \texttt{basic\_string} deduction guide refers to the \texttt{size\_type} member type of the type deduced by the deduction guide.

The types \texttt{iterator} and \texttt{const\_iterator} meet the \texttt{constexpr} iterator requirements (25.3.1).

### 23.4.3.2 General requirements

* If any operation would cause \texttt{size()} to exceed \texttt{max\_size()}, that operation throws an exception object of type \texttt{length\_error}.

* If any member function or operator of \texttt{basic\_string} throws an exception, that function or operator has no other effect on the \texttt{basic\_string} object.

Every object of type \texttt{basic\_string<\texttt{charT}, \texttt{traits}, \texttt{Allocator}>} uses an object of type \texttt{Allocator} to allocate and free storage for the contained \texttt{charT} objects as needed. The \texttt{Allocator} object used is obtained as described in 24.2.2.2. In every specialization \texttt{basic\_string<\texttt{charT}, \texttt{traits}, \texttt{Allocator}>}, the type \texttt{traits} shall meet the character traits requirements (23.2). [Note 1: Every specialization \texttt{basic\_string<\texttt{charT}, \texttt{traits}, \texttt{Allocator}>} is an allocator-aware container (24.2.2.5), but does not use the allocator’s \texttt{construct} and \texttt{destroy} member functions (24.2.1). The program is ill-formed if \texttt{Allocator::value\_type} is not the same type as \texttt{charT}. — end note]

[Note 2: The program is ill-formed if \texttt{traits::char\_type} is not the same type as \texttt{charT}. — end note]

References, pointers, and iterators referring to the elements of a \texttt{basic\_string} sequence may be invalidated by the following uses of that \texttt{basic\_string} object:

* (4.1) Passing as an argument to any standard library function taking a reference to non-const \texttt{basic\_string} as an argument.

* (4.2) Calling non-const member functions, except \texttt{operator[]}, \texttt{at}, \texttt{data}, \texttt{front}, \texttt{back}, \texttt{begin}, \texttt{rbegin}, \texttt{end}, and \texttt{rend}.

### 23.4.3.3 Constructors and assignment operators

constexpr explicit \texttt{basic\_string(const \texttt{Allocator}& \texttt{a}) noexcept;}

* Postconditions: \texttt{size()} is equal to 0.

constexpr \texttt{basic\_string(const \texttt{basic\_string}& \texttt{str});}

constexpr \texttt{basic\_string(basic\_string&& \texttt{str}) noexcept;}

Effects: Constructs an object whose value is that of \texttt{str} prior to this call.

Remarks: In the second form, \texttt{str} is left in a valid but unspecified state.

constexpr \texttt{basic\_string(const basic\_string& \texttt{str}, size\_type \texttt{pos},
const \texttt{Allocator}& \texttt{a} = Allocator());}

constexpr \texttt{basic\_string(const basic\_string& \texttt{str}, size\_type \texttt{pos}, size\_type \texttt{n},
const \texttt{Allocator}& \texttt{a} = Allocator());}

constexpr \texttt{basic\_string(basic\_string&& \texttt{str}, size\_type \texttt{pos},
const \texttt{Allocator}& \texttt{a} = Allocator());}

constexpr \texttt{basic\_string(basic\_string&& \texttt{str}, size\_type \texttt{pos}, size\_type \texttt{n},
const \texttt{Allocator}& \texttt{a} = Allocator());}

Let

* \(s\) be the value of \texttt{str} prior to this call and

* \(rlen\) be \texttt{pos} + \texttt{min(n, s.size() - pos)} for the overloads with parameter \texttt{n}, and \texttt{s.size()} otherwise.

Effects: Constructs an object whose initial value is the range \([s.data() + pos, s.data() + rlen])

Throws: \texttt{out\_of\_range} if \texttt{pos} > \texttt{s.size()}.

Remarks: For the overloads with a \texttt{basic\_string&&} parameter, \texttt{str} is left in a valid but unspecified state.

206) For example, as an argument to non-member functions \texttt{swap()} (23.4.4.3), \texttt{operator\textgreater\textgreater}() (23.4.4.4), and \texttt{getline()} (23.4.4.4), or as an argument to \texttt{basic\_string::swap()}.
**Recommended practice:** For the overloads with a `basic_string&&` parameter, implementations should avoid allocation if `s.get_allocator() == a` is true.

```cpp
template<class T>
constexpr basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());
```

**Constraints:**
- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true.
- `is_convertible_v<const T&, const charT*>` is false.

**Effects:** Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t;` and then behaves the same as:

```cpp
basic_string(sv.substr(pos, n), a);
```

```cpp
template<class T>
constexpr explicit basic_string(const T& t, const Allocator& a = Allocator());
```

**Constraints:**
- `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true.
- `is_convertible_v<const T&, const charT*>` is false.

**Effects:** Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t;` and then behaves the same as:

```cpp
basic_string(sv.data(), sv.size(), a);
```

```cpp
constexpr basic_string(const charT* s, size_type n, const Allocator& a = Allocator());
```

**Preconditions:** `[s, s + n)` is a valid range.

**Effects:** Constructs an object whose initial value is the range `[s, s + n)`.

**Postconditions:** `size()` is equal to `n`, and `traits::compare(data(), s, n)` is equal to 0.

```cpp
constexpr basic_string(const charT* s, const Allocator& a = Allocator());
```

**Constraints:**
- `Allocator` is a type that qualifies as an allocator (24.2.2.2).

**[Note 1:]** This affects class template argument deduction. —end note

**Effects:** Equivalent to:

```cpp
basic_string(s, traits::length(s), a);
```

```cpp
constexpr basic_string(size_type n, charT c, const Allocator& a = Allocator());
```

**Constraints:**
- `Allocator` is a type that qualifies as an allocator (24.2.2.2).

**[Note 2:]** This affects class template argument deduction. —end note

**Effects:** Constructs an object whose value consists of `n` copies of `c`.

```cpp
template<class InputIterator>
constexpr basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());
```

**Constraints:**
- `InputIterator` is a type that qualifies as an input iterator (24.2.2.2).

**Effects:** Constructs a string from the values in the range `[begin, end)`, as specified in 24.2.4.

```cpp
template<container-compatible-range<charT> R>
constexpr basic_string(from_range_t, R&& rg, const Allocator& = Allocator());
```

**Effects:** Constructs a string from the values in the range `rg`, as specified in 24.2.4.

```cpp
constexpr basic_string(initializer_list<charT> il, const Allocator& a = Allocator());
```

**Effects:** Equivalent to `basic_string(il.begin(), il.end(), a)`.

```cpp
constexpr basic_string(const basic_string& str, const Allocator& alloc);
```

**Effects:** Constructs an object whose value is that of `str` prior to this call. The stored allocator is constructed from `alloc`. In the second form, `str` is left in a valid but unspecified state.

**Throws:** The second form throws nothing if `alloc == str.get_allocator()`.

```cpp
template<class InputIterator, typename iterator_traits<InputIterator>::::value_type>
basic_string(InputIterator, InputIterator, Allocator = Allocator());
```
char_traits<typename iterator_traits<InputIterator>::value_type>,
Allocator>;

Constraints: InputIterator is a type that qualifies as an input iterator, and Allocator is a type that
qualifies as an allocator (24.2.2.2).

.template<class charT,
   class traits,
   class Allocator = allocator<charT>>
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;

Constraints: Allocator is a type that qualifies as an allocator (24.2.2.2).

constexpr basic_string& operator=(const basic_string& str);

Effects: If *this and str are the same object, has no effect. Otherwise, replaces the value of *this
with a copy of str.

Returns: *this.

constexpr basic_string& operator=(basic_string&& str)
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
allocator_traits<Allocator>::is_always_equal::value);

Effects: Move assigns as a sequence container (24.2.4), except that iterators, pointers and references
may be invalidated.

Returns: *this.

template<class T>
constexpr basic_string& operator=(const T& t);

Constraints:
— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:
   basic_string_view<charT, traits> sv = t;
   return assign(sv);

constexpr basic_string& operator=(const charT* s);

Effects: Equivalent to: return *this = basic_string_view<charT, traits>(s);

constexpr basic_string& operator=(charT c);

Effects: Equivalent to:
   return *this = basic_string_view<charT, traits>(addressof(c), 1);

constexpr basic_string& operator=(initializer_list<charT> il);

Effects: Equivalent to:
   return *this = basic_string_view<charT, traits>(il.begin(), il.size());

23.4.3.4 Iterator support [string.iterators]

constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first character in the string.
constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(end()).

constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(begin()).

23.4.3.5 Capacity

constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;

Returns: A count of the number of char-like objects currently in the string.
Complexity: Constant time.

constexpr size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be stored in a basic_string.
Complexity: Constant time.

constexpr void resize(size_type n, charT c);

Effects: Alters the value of *this as follows:

- If n \leq\ size(), erases the last size() - n elements.
- If n > size(), appends n - size() copies of c.

constexpr void resize(size_type n);

Effects: Equivalent to resize(n, charT()).

template<class Operation> constexpr void resize_and_overwrite(size_type n, Operation op);

Let

- o = size() before the call to resize_and_overwrite.
- k be min(o, n).
- p be a value of type charT* or charT* const, such that the range [p, p + n] is valid and this->compare(0, k, p, k) == 0 is true before the call. The values in the range [p + k, p + n] may be indeterminate (6.7.4).
- m be a value of type size_type or const size_type equal to n.
- OP be the expression std::move(op)(p, m).
- r = OP.

Mandates: OP has an integer-like type (25.3.4.4).

Preconditions:

- OP does not throw an exception or modify p or m.
- r \geq 0.
- r \leq m.
- After evaluating OP there are no indeterminate values in the range [p, p + r).

Effects: Evaluates OP, replaces the contents of *this with [p, p + r), and invalidates all pointers and references to the range [p, p + n].
Recommended practice: Implementations should avoid unnecessary copies and allocations by, for example, making p a pointer into internal storage and by restoring *(p + r) to charT() after evaluating OP.

```cpp
constexpr size_type capacity() const noexcept;
```

Returns: The size of the allocated storage in the string.

Complexity: Constant time.

```cpp
constexpr void reserve(size_type res_arg);
```

Effects: A directive that informs a basic_string of a planned change in size, so that the storage allocation can be managed accordingly. Following a call to reserve, capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve.

Throws: length_error if res_arg > max_size() or any exceptions thrown by allocator_traits<Allocator>::allocate.

```cpp
constexpr void shrink_to_fit();
```

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size().

Note 1: The request is non-binding to allow latitude for implementation-specific optimizations. — end note

It does not increase capacity(), but may reduce capacity() by causing reallocation.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

Note 2: If no reallocation happens, they remain valid. — end note

```cpp
constexpr void clear() noexcept;
```

Effects: Equivalent to: erase(begin(), end());

```cpp
[[nodiscard]] constexpr bool empty() const noexcept;
```

Effects: Equivalent to: return size() == 0;

### 23.4.3.6 Element access

```cpp
constexpr const_reference operator[](size_type pos) const;
```

```cpp
constexpr reference operator[](size_type pos);
```

Preconditions: pos <= size().

Returns: *(begin() + pos) if pos < size(). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.

Throws: Nothing.

Complexity: Constant time.

```cpp
constexpr const_reference at(size_type pos) const;
```

```cpp
constexpr reference at(size_type pos);
```

Returns: operator[](pos).

Throws: out_of_range if pos >= size().

```cpp
constexpr const charT& front() const;
```

```cpp
constexpr charT& front();
```

Preconditions: !empty().

Effects: Equivalent to: return operator[](0);

```cpp
constexpr const charT& back() const;
```

§ 23.4.3.6
constexpr charT& back();

Preconditions: !empty().

Effects: Equivalent to: return operator[](size() - 1);

23.4.3.7 Modifiers

23.4.3.7.1 basic_string::operator+=

constexpr basic_string& operator+=(const basic_string& str);

Effects: Equivalent to: return append(str);

template<class T>
constexpr basic_string& operator+=(const T& t);

Effects: Equivalent to:

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*>> is false.

Constraints:

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv);

constexpr basic_string& operator+=(const charT* s);

Effects: Equivalent to: return append(s);

constexpr basic_string& operator+=(charT c);

Effects: Equivalent to: return append(size_type{1}, c);

constexpr basic_string& operator+=(initializer_list<charT> il);

Effects: Equivalent to: return append(il);

23.4.3.7.2 basic_string::append

constexpr basic_string& append(const basic_string& str);

Effects: Equivalent to: return append(str.data(), str.size());

constexpr basic_string& append(const basic_string& str, size_type pos, size_type n = npos);

Effects: Equivalent to:

return append(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
constexpr basic_string& append(const T& t);

Constraints:

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.data(), sv.size());

template<class T>
constexpr basic_string& append(const T& t, size_type pos, size_type n = npos);

Constraints:

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*>> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.substr(pos, n));

§ 23.4.3.7.2
constexpr basic_string& append(const charT* s, size_type n);
  
  **Preconditions:** \([s, s + n)\) is a valid range.
  
  **Effects:** Appends a copy of the range \([s, s + n)\) to the string.
  
  **Returns:** *this.

constexpr basic_string& append(const charT* s);
  
  **Effects:** Equivalent to: return append(s, traits::length(s));

constexpr basic_string& append(size_type n, charT c);
  
  **Effects:** Appends \(n\) copies of \(c\) to the string.
  
  **Returns:** *this.

template<class InputIterator>
constexpr basic_string& append(InputIterator first, InputIterator last);
  
  **Constraints:** `InputIterator` is a type that qualifies as an input iterator (24.2.2.2).
  
  **Effects:** Equivalent to: return append(basic_string(first, last, get_allocator()));

template<container-compatible-range<charT> R>
constexpr basic_string& append_range(R&& rg);
  
  **Effects:** Equivalent to: return append(basic_string(from_range, std::forward<R>(rg), get_allocator()));

constexpr basic_string& append(initializer_list<charT> il);
  
  **Effects:** Equivalent to: return append(il.begin(), il.size());

constexpr void push_back(charT c);
  
  **Effects:** Equivalent to `append(size_type{1}, c)`.

§ 23.4.3.7.3  basic_string::assign  [string.assign]

constexpr basic_string& assign(const basic_string& str);
  
  **Effects:** Equivalent to: return *this = str;

constexpr basic_string& assign(basic_string&& str)
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
  allocator_traits<Allocator>::is_always_equal::value);
  
  **Effects:** Equivalent to: return *this = std::move(str);

constexpr basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);
  
  **Effects:** Equivalent to:
  
  assign(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
constexpr basic_string& assign(const T& t);
  
  **Constraints:**

  (4.1) `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
  
  (4.2) `is_convertible_v<const T&, const charT*>` is false.

  **Effects:** Equivalent to:

  basic_string_view<charT, traits> sv = t;
  return assign(sv.data(), sv.size());

template<class T>
constexpr basic_string& assign(const T& t, size_type pos, size_type n = npos);
  
  **Constraints:**

  (6.1) `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and

§ 23.4.3.7.3
is_convertible_v<const T& , const charT*> is false.

Effects: Equivalent to:

    basic_string_view<charT, traits> sv = t;
    return assign(sv.substr(pos, n));

constexpr basic_string& assign(const charT* s, size_type n);

Preconditions: [s, s + n) is a valid range.

Effects: Replaces the string controlled by *this with a copy of the range [s, s + n).

Returns: *this.

constexpr basic_string& assign(const charT* s);

Effects: Equivalent to: return assign(s, traits::length(s));

constexpr basic_string& assign(initializer_list<charT> il);

Effects: Equivalent to: return assign(il.begin(), il.size());

constexpr basic_string& assign(size_type n, charT c);

Effects: Equivalent to:
    clear();
    resize(n, c);
    return *this;

template<class InputIterator>
constexpr basic_string& assign(InputIterator first, InputIterator last);

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.2).

Effects: Equivalent to: return assign(basic_string(first, last, get_allocator()));

template<container-compatible-range<charT> R>
constexpr basic_string& assign_range(R&& rg);

Effects: Equivalent to: return assign(basic_string(from_range, std::forward<R>(rg), get_allocator()));

23.4.3.7.4 basic_string::insert

constexpr basic_string& insert(size_type pos, const basic_string& str);

Effects: Equivalent to: return insert(pos, str.data(), str.size());

constexpr basic_string& insert(size_type pos1, const basic_string& str,
    size_type pos2, size_type n = npos);

Effects: Equivalent to:
    return insert(pos1, basic_string_view<charT, traits>(str), pos2, n);

template<class T>
constexpr basic_string& insert(size_type pos, const T& t);

Constraints:

(3.1)     — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2)     — is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
    basic_string_view<charT, traits> sv = t;
    return insert(pos, sv.data(), sv.size());

template<class T>
constexpr basic_string& insert(size_type pos1, const T& t,
    size_type pos2, size_type n = npos);

Constraints:

(5.1)     — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2) \hspace{1cm} \text{is\_convertible\_v<const T&, const charT*> is false.}

6 Effects: Equivalent to:
\hspace{1cm} basic\_string\_view<\text{charT}, \text{traits}> sv = t;
\hspace{1cm} return insert(pos1, sv.substr(pos2, n));

\text{constexpr basic\_string& insert(size\_type pos, const charT* s, size\_type n);} 

7 Preconditions: \([s, s + n)\) is a valid range.

8 Effects: Inserts a copy of the range \([s, s + n)\) immediately before the character at position \text{pos} if \text{pos} < \text{size()}, or otherwise at the end of the string.

9 Returns: *this.

10 Throws:
\hspace{1cm} \text{out\_of\_range} if \text{pos} > \text{size()},
\hspace{1cm} \text{length\_error} if \text{n} > \text{max\_size()} - \text{size()}, or
\hspace{1cm} any exceptions thrown by allocator\_traits<\text{Allocator}>::allocate.

\text{constexpr basic\_string& insert(size\_type pos, const charT* s);} 

11 Effects: Equivalent to: return insert(pos, s, traits::length(s));

\text{constexpr basic\_string& insert(size\_type pos, size\_type n, charT c);} 

12 Effects: Inserts \text{n} copies of \text{c} before the character at position \text{pos} if \text{pos} < \text{size()}, or otherwise at the end of the string.

13 Returns: *this.

14 Throws:
\hspace{1cm} \text{out\_of\_range} if \text{pos} > \text{size()},
\hspace{1cm} \text{length\_error} if \text{n} > \text{max\_size()} - \text{size()}, or
\hspace{1cm} any exceptions thrown by allocator\_traits<\text{Allocator}>::allocate.

\text{constexpr iterator insert(const\_iterator p, charT c);} 

15 Preconditions: \text{p} is a valid iterator on *this.

16 Effects: Inserts a copy of \text{c} at the position \text{p}.

17 Returns: An iterator which refers to the inserted character.

\text{constexpr iterator insert(const\_iterator p, size\_type n, charT c);} 

18 Preconditions: \text{p} is a valid iterator on *this.

19 Effects: Inserts \text{n} copies of \text{c} at the position \text{p}.

20 Returns: An iterator which refers to the first inserted character, or \text{p} if \text{n} == 0.

\text{template<class Input\_Iterator>}
\hspace{1cm} \text{constexpr iterator insert(const\_iterator p, Input\_Iterator first, Input\_Iterator last);} 

21 Constraints: \text{Input\_Iterator} is a type that qualifies as an input iterator (24.2.2.2).

22 Preconditions: \text{p} is a valid iterator on *this.

23 Effects: Equivalent to insert(p - begin(), basic\_string(first, last, get\_allocator())).

24 Returns: An iterator which refers to the first inserted character, or \text{p} if first == last.

\text{template<container\_compatible\_range<\text{charT}> R>}
\hspace{1cm} \text{constexpr iterator insert\_range(const\_iterator p, R&& rg);} 

25 Preconditions: \text{p} is a valid iterator on *this.

26 Effects: Equivalent to insert(p - begin(), basic\_string(from\_range, std::forward<R>(rg), get\_allocator())).

27 Returns: An iterator which refers to the first inserted character, or \text{p} if \text{rg} is empty.
constexpr iterator insert(const_iterator p, initializer_list<charT> il);

Effects: Equivalent to: return insert(p, il.begin(), il.end());

23.4.3.7.5 basic_string::erase

constexpr basic_string& erase(size_type pos = 0, size_type n = npos);

Effects: Determines the effective length xlen of the string to be removed as the smaller of n and size() - pos. Removes the characters in the range [begin() + pos, begin() + pos + xlen).
Returns: *this.
Throws: out_of_range if pos > size().

constexpr iterator erase(const_iterator p);
Preconditions: p is a valid dereferenceable iterator on *this.
Effects: Removes the character referred to by p.
Returns: An iterator which points to the element immediately following p prior to the element being erased. If no such element exists, end() is returned.
Throws: Nothing.

constexpr iterator erase(const_iterator first, const_iterator last);
Preconditions: first and last are valid iterators on *this. [first, last) is a valid range.
Effects: Removes the characters in the range [first, last).
Returns: An iterator which points to the element pointed to by last prior to the other elements being erased. If no such element exists, end() is returned.
Throws: Nothing.

constexpr void pop_back();
Preconditions: !empty().
Effects: Equivalent to erase(end() - 1).
Throws: Nothing.

23.4.3.7.6 basic_string::replace

constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str);
Effects: Equivalent to: return replace(pos1, n1, str.data(), str.size());

constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str, size_type pos2, size_type n2 = npos);
Effects: Equivalent to:
return replace(pos1, n1, basic_string_view<charT, traits>(str).substr(pos2, n2));

template<class T>
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t);

Constraints:
(3.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2) is_convertible_v<const T&, const charT*> is false.
Effects: Equivalent to:
basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.data(), sv.size());

template<class T>
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t, size_type pos2, size_type n2 = npos);

Constraints:
(5.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
is_convertible_v<const T&, const charT*> is false.

**Effects:** Equivalent to:

```cpp
class string_view
{
public:
    string_view(size_type pos1, size_type n1, const charT* s, size_type n2);
    string_view(size_type pos, size_type n, const charT* s);
    string_view(const_iterator i1, const_iterator i2, const charT* s);
    string_view(size_type pos1, size_type n1, const charT* s, size_type n2);
    string_view(const_iterator i1, const_iterator i2, const basic_string& str);
    string_view(const_iterator i1, const_iterator i2, const charT* s, size_type n);
    string_view(const_iterator i1, const_iterator i2, size_type n, charT c);
    string_view(const_iterator i1, const_iterator i2, size_type n, const charT* s);
    string_view(const_iterator i1, const_iterator i2, const T& t);

    string_view& replace(size_type pos1, size_type n1, const charT* s, size_type n2);
    string_view& replace(size_type pos, size_type n, const charT* s);
    string_view& replace(size_type pos1, size_type n1, const charT* s);
    string_view& replace(const_iterator i1, const_iterator i2, const basic_string& str);`
template<class InputIterator>
constexpr basic_string& replace(const_iterator i1, const_iterator i2,
  InputIterator j1, InputIterator j2);

23 CONSTRAINTS: InputIterator is a type that qualifies as an input iterator (24.2.2.2).

24 EFFECTS: Equivalent to: return replace(i1, i2, basic_string(j1, j2, get_allocator()));

template<container-compatible-range<CharT> R>
constexpr basic_string& replace_with_range(const_iterator i1, const_iterator i2, R&& rg);

25 EFFECTS: Equivalent to:
  return replace(i1, i2, basic_string(from_range, std::forward<R>(rg), get_allocator()));

constexpr basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<CharT> il);

26 EFFECTS: Equivalent to: return replace(i1, i2, il.begin(), il.size());

23.4.3.7.7 basic_string::copy [string.copy]

constexpr size_type copy(CharT* s, size_type n, size_type pos = 0) const;

1 EFFECTS: Equivalent to: return basic_string_view<CharT, Traits>(*this).copy(s, n, pos);
  [Note 1: This does not terminate s with a null object. — end note]

23.4.3.7.8 basic_string::swap [string.swap]

constexpr void swap(basic_string& s)
  noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
    allocator_traits<Allocator>::is_always_equal::value);

1 PRECONDITIONS: allocator_traits<Allocator>::propagate_on_container_swap::value is true or
    get_allocator() == s.get_allocator().

2 POSTCONDITIONS: *this contains the same sequence of characters that was in s, s contains the same
    sequence of characters that was in *this.

3 THROWS: Nothing.

4 COMPLEXITY: Constant time.

23.4.3.8 String operations [string.ops]
23.4.3.8.1 Accessors [string.accessors]

constexpr const CharT* c_str() const noexcept;

1 RETURNS: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

2 COMPLEXITY: Constant time.

3 REMARKS: The program shall not modify any of the values stored in the character array; otherwise, the
    behavior is undefined.

constexpr CharT* data() noexcept;

4 RETURNS: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

5 COMPLEXITY: Constant time.

6 REMARKS: The program shall not modify the value stored at p + size() to any value other than
    charT(); otherwise, the behavior is undefined.

constexpr operator basic_string_view<CharT, Traits>() const noexcept;

7 EFFECTS: Equivalent to: return basic_string_view<CharT, Traits>(data(), size());

constexpr allocator_type get_allocator() const noexcept;

8 RETURNS: A copy of the Allocator object used to construct the string or, if that allocator has been
    replaced, a copy of the most recent replacement.
23.4.3.8.2 Searching

Let \( F \) be one of `find`, `rfind`, `find_first_of`, `find_last_of`, `find_first_not_of`, and `find_last_not_of`. Each member function of the form

\[
\text{constexpr size_type } F(\text{const basic_string}& \text{ str, size_type pos}) \text{ const noexcept};
\]

has effects equivalent to:

\[
\text{return } F(\text{basic_string_view<charT, traits>(str), pos});
\]

Each member function of the form

\[
\text{constexpr size_type } F(\text{const charT}*& s, \text{size_type pos}) \text{ const};
\]

has effects equivalent to:

\[
\text{return } F(\text{basic_string_view<charT, traits>(s), pos});
\]

Each member function of the form

\[
\text{constexpr size_type } F(\text{const charT}*& s, \text{size_type pos, size_type n}) \text{ const};
\]

has effects equivalent to:

\[
\text{return } F(\text{basic_string_view<charT, traits>(s, n), pos});
\]

Each member function of the form

\[
\text{constexpr size_type } F(\text{charT c, size_type pos}) \text{ const noexcept};
\]

has effects equivalent to:

\[
\text{return } F(\text{basic_string_view<charT, traits>(addressof(c), 1), pos});
\]

Constraints:

(2.1) \( \text{is_convertible_v<const T&, basic_string_view<charT, traits>>} \) is true and
(2.2) \( \text{is_convertible_v<const T&, const charT*}} \) is false.

Effects: Let \( G \) be the name of the function. Equivalent to:

\[
\text{basic_string_view<charT, traits> s = *this, sv = t};
\]

\[
\text{return s.} \ G(\text{sv, pos});
\]

Remarks: The exception specification is equivalent to \( \text{is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>} \).

23.4.3.8.3 basic_string::substr

\[
\text{constexpr basic_string substr(size_type pos = 0, size_type n = npos) const &;}
\]

Effects: Equivalent to:

\[
\text{return basic_string(*this, pos, n);}
\]

\[
\text{constexpr basic_string substr(size_type pos = 0, size_type n = npos) &&;}
\]

Effects: Equivalent to:

\[
\text{return basic_string(std::move(*this), pos, n);}
\]

23.4.3.8.4 basic_string::compare

\[
\text{template<class T>}
\]

\[
\text{constexpr int compare(const T& t) const noexcept(see below);}
\]

Constraints:

(1.1) \( \text{is_convertible_v<const T&, basic_string_view<charT, traits>>} \) is true and
(1.2) \( \text{is_convertible_v<const T&, const charT*}} \) is false.
Effects: Equivalent to: `return basic_string_view<charT, traits>(*this).compare(t);`

Remarks: The exception specification is equivalent to `is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>`.

```cpp
template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t) const;
```

Constraints:

1. `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
2. `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(*this).substr(pos1, n1).compare(t);
```

```cpp
template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t, size_type pos2, size_type n2 = npos) const;
```

Constraints:

1. `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
2. `is_convertible_v<const T&, const charT*>` is false.

Effects: Equivalent to:

```
basic_string_view<charT, traits> s = *this, sv = t;
return s.substr(pos1, n1).compare(sv.substr(pos2, n2));
```

```cpp
constexpr int compare(const basic_string& str) const noexcept;
```

Effects: Equivalent to:

```
return compare(basic_string_view<charT, traits>(str));
```

```cpp
constexpr int compare(size_type pos1, size_type n1, const basic_string& str) const;
```

Effects: Equivalent to:

```
return compare(pos1, n1, basic_string_view<charT, traits>(str));
```

```cpp
constexpr int compare(size_type pos1, size_type n1, const charT* s) const;
```

Effects: Equivalent to:

```
return compare(pos1, n1, basic_string_view<charT, traits>(s, n2));
```

23.4.3.8.5 `basic_string::starts_with`

```cpp
constexpr bool starts_with(basic_string_view<charT, traits> x) const noexcept;
```

Effects: Equivalent to:

```
return basic_string_view<charT, traits>(data(), size()).starts_with(x);
```

23.4.3.8.6 `basic_string::ends_with`

```cpp
constexpr bool ends_with(basic_string_view<charT, traits> x) const noexcept;
```

Effects: Equivalent to:

```
return ends_with(basic_string_view<charT, traits>(data(), size()));
```
return basic_string_view<charT, traits>(data(), size()).ends_with(x);

23.4.3.8.7 basic_string::contains

constexpr bool contains(basic_string_view<charT, traits> x) const noexcept;
constexpr bool contains(charT x) const noexcept;
constexpr bool contains(const charT* x) const;

1 Effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).contains(x);

23.4.4 Non-member functions

23.4.4.1 operator+

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

1 Effects: Equivalent to:

basic_string<charT, traits, Allocator> r = lhs;
r.append(rhs);
return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>&& lhs, const charT* rhs);

1 Effects: Equivalent to:

lhs.append(rhs);

return std::move(lhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, basic_string<charT, traits, Allocator>&& rhs);

3 Effects: Equivalent to:

lhs.append(rhs);

return std::move(lhs);

except that both lhs and rhs are left in valid but unspecified states.

[Note 1: If lhs and rhs have equal allocators, the implementation can move from either. — end note]

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>&& lhs, basic_string<charT, traits, Allocator>&& rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, basic_string<charT, traits, Allocator>&& rhs);

4 Effects: Equivalent to:

rhs.insert(0, lhs);

return std::move(rhs);
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
5  Effects: Equivalent to:
    basic_string<charT, traits, Allocator> r = rhs;
    r.insert(0, lhs);
    return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, const basic_string<charT, traits, Allocator>& rhs);
6  Effects: Equivalent to:
    basic_string<charT, traits, Allocator> r = rhs;
    r.insert(r.begin(), lhs);
    return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, basic_string<charT, traits, Allocator>&& rhs);
7  Effects: Equivalent to:
    rhs.insert(rhs.begin(), lhs);
    return std::move(rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, charT rhs);
8  Effects: Equivalent to:
    basic_string_view<charT, traits>(lhs)
    op
    basic_string_view<charT, traits>(rhs);

23.4.4.2 Non-member comparison operator functions

template<class charT, class traits, class Allocator>
constexpr bool
operator==(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
constexpr
see below
operator<=>(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;

23.4.4.3 swap

Effects: Let op be the operator. Equivalent to:
            return basic_string_view<charT, traits>(lhs) op basic_string_view<charT, traits>(rhs);
template<class charT, class traits, class Allocator>
constexpr void
swap(basic_string<charT, traits, Allocator>& lhs,
    basic_string<charT, traits, Allocator>& rhs)
noexcept(noexcept(lhs.swap(rhs)));

Effects: Equivalent to lhs.swap(rhs).

23.4.4.4 Inserters and extractors  [string.io]

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);

Effects: Behaves as a formatted input function (31.7.5.3.1). After constructing a sentry object, if
the sentry object returns true when converted to a value of type bool, calls str.erase() and then
extracts characters from is and appends them to str as if by calling str.append(1, c). If is.width() is
greater than zero, the maximum number n of characters appended is is.width(); otherwise n is
str.max_size(). Characters are extracted and appended until any of the following occurs:

(1.1) — n characters are stored;
(1.2) — end-of-file occurs on the input sequence;
(1.3) — isspace(c, is.getloc()) is true for the next available input character c.

After the last character (if any) is extracted, is.width(0) is called and the sentry object is destroyed.
If the function extracts no characters, ios_base::failbit is set in the input function’s local error
state before setstate is called.

Returns: is.

template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
    const basic_string<charT, traits, Allocator>& str);

Effects: Equivalent to: return os << basic_string_view<charT, traits>(str);

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>& is,
    basic_string<charT, traits, Allocator>& str,
    charT delim);

Effects: Behaves as an unformatted input function (31.7.5.4), except that it does not affect the value
returned by subsequent calls to basic_istream::gcount(). After constructing a sentry object, if
the sentry object returns true when converted to a value of type bool, calls str.erase() and then
extracts characters from is and appends them to str as if by calling str.append(1, c) until any of
the following occurs:

(6.1) — end-of-file occurs on the input sequence;
(6.2) — traits::eq(c, delim) for the next available input character c (in which case, c is extracted but
not appended);
(6.3) — str.max_size() characters are stored (in which case, ios_base::failbit is set in the input
function’s local error state).

The conditions are tested in the order shown. In any case, after the last character is extracted, the
sentry object is destroyed.
If the function extracts no characters, ios_base::failbit is set in the input function’s local error
state before setstate is called.

Returns: is.
template<class charT, class traits, class Allocator>
    basic_istream<charT, traits>&
    getline(basic_istream<charT, traits>&& is,
    basic_string<charT, traits, Allocator>& str);

template<class charT, class traits, class Allocator>
    basic_istream<charT, traits>&
    getline(basic_istream<charT, traits, Allocator>&& is,
    basic_string<charT, traits, Allocator>& str);

10 Returns: getline(is, str, is.widen('\n')).

23.4.4.5 Erasure

template<class charT, class traits, class Allocator, class U>
    constexpr typename basic_string<charT, traits, Allocator>::size_type
    erase(basic_string<charT, traits, Allocator>& c, const U& value);

Effects: Equivalent to:
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

template<class charT, class traits, class Allocator, class Predicate>
    constexpr typename basic_string<charT, traits, Allocator>::size_type
    erase_if(basic_string<charT, traits, Allocator>& c, Predicate pred);

Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

23.4.5 Numeric conversions

int stoi(const string& str, size_t* idx = nullptr, int base = 10);
long stol(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const string& str, size_t* idx = nullptr, int base = 10);
long long stoll(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = nullptr, int base = 10);

Effects: The first two functions call strtol(str.c_str(), ptr, base), and the last three functions call
strtoul(str.c_str(), ptr, base), strtoll(str.c_str(), ptr, base), and strtoull(str.c_str(), ptr, base), respectively. Each function returns the converted result, if any. The argument
ptr designates a pointer to an object internal to the function that is used to determine what to store
at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx
the index of the first unconverted element of str.

Returns: The converted result.

Throws: invalid_argument if strtol, strtoul, or strtoull reports that no conversion can
be performed. Throws out_of_range if strtol, strtoul, or strtoull sets errno to ERANGE,
or if the converted value is outside the range of representable values for the return type.

float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);

Effects: These functions call strtof(str.c_str(), ptr), strtod(str.c_str(), ptr), and strtold(
str.c_str(), ptr), respectively. Each function returns the converted result, if any. The argument
ptr designates a pointer to an object internal to the function that is used to determine what to store
at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx
the index of the first unconverted element of str.

Returns: The converted result.
Throws: invalid_argument if `strtof`, `strtod`, or `strtold` reports that no conversion can be performed. Throws out_of_range if `strtof`, `strtod`, or `strtold` sets `errno` to ERANGE or if the converted value is outside the range of representable values for the return type.

```cpp
string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(unsigned long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);
```

Returns: `format("{}", val)`.

```cpp
int stoi(const wstring& str, size_t* idx = nullptr, int base = 10);
long stol(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = nullptr, int base = 10);
long long stoll(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = nullptr, int base = 10);
```

Effects: The first two functions call `wcstol(str.c_str(), ptr, base)`, and the last three functions call `wcstoul(str.c_str(), ptr, base)`, `wcstoll(str.c_str(), ptr, base)`, and `wcstoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != `nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

```cpp
float stof(const wstring& str, size_t* idx = nullptr);
double stod(const wstring& str, size_t* idx = nullptr);
long double stold(const wstring& str, size_t* idx = nullptr);
```

Effects: These functions call `wcstof(str.c_str(), ptr)`, `wcstod(str.c_str(), ptr)`, and `wcstold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != `nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

```cpp
wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);
wstring to_wstring(long double val);
```

Returns: `format(L"{}", val)`.

### 23.4.6 Hash support

[.DataGridViewTextBoxColumn](basic.string.hash)

```cpp
template<class A> struct hash<basic_string<char, char_traits<char>, A>>;
template<class A> struct hash<basic_string<char8_t, char_traits<char8_t>, A>>;
template<class A> struct hash<basic_string<char16_t, char_traits<char16_t>, A>>;
template<class A> struct hash<basic_string<char32_t, char_traits<char32_t>, A>>;
```
template<class A> struct hash<basic_string<wchar_t, char_traits<wchar_t>, A>>;

1 If \( S \) is one of these string types, \( SV \) is the corresponding string view type, and \( s \) is an object of type \( S \), then
\[
\text{hash}<S>()(s) == \text{hash}<SV>()(SV(s)).
\]

### 23.4.7 Suffix for basic_string literals

`constexpr string operator"s(const char* str, size_t len);`

1 `Returns:` `string{str, len}.`

`constexpr u8string operator"s(const char8_t* str, size_t len);`

2 `Returns:` `u8string{str, len}.`

`constexpr u16string operator"s(const char16_t* str, size_t len);`

3 `Returns:` `u16string{str, len}.`

`constexpr u32string operator"s(const char32_t* str, size_t len);`

4 `Returns:` `u32string{str, len}.`

`constexpr wstring operator"s(const wchar_t* str, size_t len);`

5 `Returns:` `wstring{str, len}.`

6 [Note 1: The same suffix \( s \) is used for \texttt{chrono::duration} literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

### 23.5 Null-terminated sequence utilities

#### 23.5.1 Header `<cctype>` synopsis

```c
namespace std {
    int isalnum(int c);
    int isalpha(int c);
    int isblank(int c);
    int iscntrl(int c);
    int isdigit(int c);
    int isgraph(int c);
    int islower(int c);
    int isprint(int c);
    int ispunct(int c);
    int isspace(int c);
    int isupper(int c);
    int isxdigit(int c);
    int tolower(int c);
    int toupper(int c);
}
```

1 The contents and meaning of the header `<cctype>` are the same as the C standard library header `<ctype.h>`.

23.5.6 Multibyte / wide string and character conversion functions

```c
// 23.5.6, multibyte / wide string and character conversion functions
int mbsinit(const mbstate_t* ps);
size_t mblen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* w, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcsrtombs(char* s, const wchar_t* pwc, size_t n, mbstate_t* ps);
```

1 The contents and meaning of the header `<cwchar>` are the same as the C standard library header `<wchar.h>`, except that it does not declare a type `wchar_t`.

2 [Note 1: The functions `wcschr`, `wcsbbrk`, `wcsrchr`, `wcsstr`, and `wmemchr` have different signatures in this document, but they have the same behavior as in the C standard library (16.2). — end note]

See also: ISO/IEC 9899:2018, 7.29

23.5.5 Header `<cuchar>` synopsis

```c
namespace std {
    using mbstate_t = see below;
    using size_t = see 17.2.4;

    size_t mbtowc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);
    size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);
    size_t mbtowc16(char16_t* pc16, const char* s, size_t n, mbstate_t* ps);
    size_t c16rtomb(char* s, char16_t c16, mbstate_t* ps);
    size_t mbtowc32(char32_t* pc32, const char* s, size_t n, mbstate_t* ps);
    size_t c32rtomb(char* s, char32_t c32, mbstate_t* ps);
}
```

1 The contents and meaning of the header `<cuchar>` are the same as the C standard library header `<uchar.h>`, except that it declares the additional `mbtowc8` and `c8rtomb` functions and does not declare types `char16_t` nor `char32_t`.

See also: ISO/IEC 9899:2018, 7.28

23.5.6 Multibyte / wide string and character conversion functions

```c
int mbsinit(const mbstate_t* ps);
int mblen(const char* s, size_t n);
size_t mbstowcs(wchar_t* pwc, const char* s, size_t n);
size_t wcsrtombs(char* s, wchar_t wc, mbstate_t* ps);
```

2 **Effects**: These functions have the semantics specified in the C standard library.

See also: ISO/IEC 9899:2018, 7.22.7.1, 7.22.8, 7.29.6.2.1

```c
int mbtowc(wchar_t* pwc, const char* s, size_t n);
int wcrtomb(char* s, wchar_t wc);
```

3 **Effects**: These functions have the semantics specified in the C standard library.

4 **Remarks**: Calls to these functions may introduce a data race (16.4.6.10) with other calls to the same function.

See also: ISO/IEC 9899:2018, 7.22.7

```c
size_t mblen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
```
size_t wcrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);

Effects: These functions have the semantics specified in the C standard library.

Remarks: Calling these functions with an mbstate_t* argument that is a null pointer value may introduce a data race (16.4.6.10) with other calls to the same function with an mbstate_t* argument that is a null pointer value.

See also: ISO/IEC 9899:2018, 7.29.6.3

size_t mbtowc(char* pc8, const char* s, size_t n, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to mbtowc(nullptr, "", 1, ps). Otherwise, the function inspects at most n bytes beginning with the byte pointed to by s to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding UTF-8 code units and then, if pc8 is not a null pointer, stores the value of the first (or only) such code unit in the object pointed to by pc8. Subsequent calls will store successive UTF-8 code units without consuming any additional input until all the code units have been stored. If the corresponding Unicode character is U+0000 NULL, the resulting state described is the initial conversion state.

Returns: The first of the following that applies (given the current conversion state):

(8.1) 0, if the next n or fewer bytes complete the multibyte character that corresponds to the U+0000 NULL Unicode character (which is the value stored).
(8.2) between 1 and n (inclusive), if the next n or fewer bytes complete a valid multibyte character (whose first (or only) code unit is stored); the value returned is the number of bytes that complete the multibyte character.
(8.3) (size_t)(-3), if the next code unit resulting from a previous call has been stored (no bytes from the input have been consumed by this call).
(8.4) (size_t)(-2), if the next n bytes contribute to an incomplete (but potentially valid) multibyte character, and all n bytes have been processed (no value is stored).
(8.5) (size_t)(-1), if an encoding error occurs, in which case the next n or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored); the value of the macro EILSEQ is stored in errno, and the conversion state is unspecified.

size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to c8rtomb(buf, u8'0', ps) where buf is an internal buffer. Otherwise, if c8 completes a sequence of valid UTF-8 code units, determines the number of bytes needed to represent the multibyte character (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by s. At most MB_CUR_MAX bytes are stored. If the multibyte character is a null character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

Returns: The number of bytes stored in the array object (including any shift sequences). If c8 does not contribute to a sequence of char8_t corresponding to a valid multibyte character, the value of the macro EILSEQ is stored in errno, (size_t)(-1) is returned, and the conversion state is unspecified.

Remarks: Calls to c8rtomb with a null pointer argument for s may introduce a data race (16.4.6.10) with other calls to c8rtomb with a null pointer argument for s.
24 Containers library

24.1 General

This Clause describes components that C++ programs may use to organize collections of information. The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 82.

24.2 Requirements

24.2.1 Preamble

Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects.

[Example 1: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. —end example]

Allocator-aware containers (24.2.2.5) other than basic_string construct elements using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroy elements using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (20.2.9.3), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container.

[Note 1: This means, for example, that a node-based container would need to construct nodes containing aligned buffers and call construct to place the element into the buffer. —end note]

24.2.2 General containers

24.2.2.1 Introduction

In subclause 24.2.2,

(1.1) — X denotes a container class containing objects of type T,
(1.2) — a denotes a value of type X,
(1.3) — b and c denote values of type (possibly const) X,
(1.4) — i and j denote values of type (possibly const) X::iterator,
(1.5) — u denotes an identifier,
(1.6) — v denotes an lvalue of type (possibly const) X or an rvalue of type const X,
(1.7) — s and t denote non-const lvalues of type X, and
(1.8) — rv denotes a non-const rvalue of type X.

The following exposition-only concept is used in the definition of containers:

```cpp
template<class R, class T>
concept container-compatible-range = // exposition only
ranges::input_range<R> && convertible_to<ranges::range_reference_t<R>, T>;
```
24.2.2.2 Container requirements

A type \( X \) meets the container requirements if the following types, statements, and expressions are well-formed and have the specified semantics.

\[
\text{typename } X \text{::value_type} \\
\text{Result: } T \\
\text{Preconditions: } T \text{ is Cpp17Erasable from } X \text{ (see 24.2.2.5, below).}
\]

\[
\text{typename } X \text{::reference} \\
\text{Result: } T&
\]

\[
\text{typename } X \text{::const_reference} \\
\text{Result: } \text{const } T&
\]

\[
\text{typename } X \text{::iterator} \\
\text{Result: A type that meets the forward iterator requirements (25.3.5.5) with value type } T. \text{ The type } X \text{::iterator is convertible to } X \text{::const_iterator.}
\]

\[
\text{typename } X \text{::const_iterator} \\
\text{Result: A type that meets the requirements of a constant iterator and those of a forward iterator with value type } T.
\]

\[
\text{typename } X \text{::difference_type} \\
\text{Result: A signed integer type, identical to the difference type of } X \text{::iterator and } X \text{::const_iterator.}
\]

\[
\text{typename } X \text{::size_type} \\
\text{Result: An unsigned integer type that can represent any non-negative value of } X \text{::difference_type.}
\]

\[
X u; \\
X u = X();
\]

\[
\text{Postconditions: } u.\text{empty()} \\
\text{Complexity: Constant.}
\]

\[
X u(v); \\
X u = v;
\]

\[
\text{Preconditions: } T \text{ is Cpp17CopyInsertable into } X \text{ (see below).} \\
\text{Postconditions: } u == v. \\
\text{Complexity: Linear.}
\]

\[
X u(rv); \\
X u = rv;
\]

\[
\text{Postconditions: } u \text{ is equal to the value that } rv \text{ had before this construction.} \\
\text{Complexity: Linear for array and constant for all other standard containers.}
\]

\[
t = v; \\
\text{Result: } X&. \\
\text{Postconditions: } t == v. \\
\text{Complexity: Linear.}
\]

\[
t = rv \\
\text{Result: } X&. \\
\text{Effects: All existing elements of } t \text{ are either move assigned to or destroyed.} \\
\text{Postconditions: If } t \text{ and } rv \text{ do not refer to the same object, } t \text{ is equal to the value that } rv \text{ had before this assignment.} \\
\text{Complexity: Linear.}
\]
a. \textendash X()

\textbf{Result:} void.
\textbf{Effects:} Destroys every element of a; any memory obtained is deallocated.
\textbf{Complexity:} Linear.

\textbf{b.begin()}

\textbf{Result:} iterator; const_iterator for constant b.
\textbf{Returns:} An iterator referring to the first element in the container.
\textbf{Complexity:} Constant.

\textbf{b.end()}

\textbf{Result:} iterator; const_iterator for constant b.
\textbf{Returns:} An iterator which is the past-the-end value for the container.
\textbf{Complexity:} Constant.

\textbf{b.cbegin()}

\textbf{Result:} const_iterator.
\textbf{Returns:} \texttt{const\_cast<X\ const\&>(b).begin()}
\textbf{Complexity:} Constant.

\textbf{b.cend()}

\textbf{Result:} const_iterator.
\textbf{Returns:} \texttt{const\_cast<X\ const\&>(b).end()}
\textbf{Complexity:} Constant.

\textbf{i <=> j}

\textbf{Result:} strong\_ordering.
\textbf{Constraints:} X::iterator meets the random access iterator requirements.
\textbf{Complexity:} Constant.

\textbf{c == b}

\textbf{Preconditions:} T meets the Cpp17EqualityComparable requirements.
\textbf{Result:} bool.
\textbf{Returns:} \texttt{equal(c.begin(), c.end(), b.begin(), b.end())}

[\textit{Note 1:} The algorithm \texttt{equal} is defined in \texttt{27.6.13.} \textendash \textit{end note}]
\textbf{Complexity:} Constant if \texttt{c.size()} \texttt{!=} \texttt{b.size()}, linear otherwise.
\textbf{Remarks:} \texttt{==} is an equivalence relation.

\textbf{c != b}

\textbf{Effects:} Equivalent to \texttt{!(c == b)}.

\textbf{t.swap(s)}

\textbf{Result:} void.
\textbf{Effects:} Exchanges the contents of t and s.
\textbf{Complexity:} Linear for array and constant for all other standard containers.

\textbf{swap(t, s)}

\textbf{Effects:} Equivalent to \texttt{t.swap(s)}.

\textbf{c.size()}

\textbf{Result:} size\_type.
Returns: `distance(c.begin(), c.end())`, i.e., the number of elements in the container.

Complexity: Constant.

Remarks: The number of elements is defined by the rules of constructors, inserts, and erases.

c.max_size()

Result: `size_type`.

Returns: `distance(begin(), end())` for the largest possible container.

Complexity: Constant.

c.empty()

Result: `bool`.

Returns: `c.begin() == c.end()`.

Complexity: Constant.

Remarks: If the container is empty, then `c.empty()` is `true`.

In the expressions

```cpp
i == j
i != j
i < j
i <= j
i >= j
i > j
i <=> j
i - j
```

where `i` and `j` denote objects of a container’s `iterator` type, either or both may be replaced by an object of the container’s `const_iterator` type referring to the same element with no change in semantics.

Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.4.4.6).

[Note 2: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type `P` or `pointer_traits<>::template rebind<unspecified>`, where `P` is `allocator_traits<>::pointer`. — end note]

Copy constructors for these container types obtain an allocator by calling `allocator_traits<>::select_on_container_copy_construction` on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a `const allocator_type&` argument.

[Note 3: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — end note]

A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or `swap()`. Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if

```cpp
(64.1) allocator_traits<>::propagate_on_container_copy_assignment::value,
(64.2) allocator_traits<>::propagate_on_container_move_assignment::value, or
(64.3) allocator_traits<>::propagate_on_container_swap::value
```

is `true` within the implementation of the corresponding container operation. In all container types defined in this Clause, the member `get_allocator()` returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression `a.swap(b)`, for containers `a` and `b` of a standard container type other than `array`, shall exchange the values of `a` and `b` without invoking any move, copy, or swap operations on the individual container elements. Any `Compare`, `Pred`, or `Hash` types belonging to `a` and `b` shall meet the `Cpp17Swappable` requirements and shall be exchanged by calling `swap` as described in 16.4.4.3. If `allocator_traits<>::propagate_on_container_swap::value` is `true`, then `allocator_type` shall meet the `Cpp17Swappable` requirements and the allocators of `a` and `b` shall also be exchanged by calling `swap` as described in 16.4.4.3.
Otherwise, the allocators shall not be swapped, and the behavior is undefined unless `a.get_allocator() == b.get_allocator()`. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value `a.end()` before the swap will have value `b.end()` after the swap.

Unless otherwise specified (see 24.2.7.2, 24.2.8.2, 24.3.8.4, and 24.3.11.5) all container types defined in this Clause meet the following additional requirements:

1. If an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.
2. If an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.
3. No `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.
4. No `swap()` function throws an exception.
5. No `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

[Note 4: The `end()` iterator does not refer to any element, so it can be invalidated. — end note]

67 Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

68 A **contiguous container** is a container whose member types `iterator` and `const_iterator` meet the `Cpp17RandomAccessIterator` requirements (25.3.5.7) and model `contiguous_iterator` (25.3.4.14).

69 The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type `A` shall not qualify as an allocator unless it meets both of the following conditions:

- The qualified-id `A::value_type` is valid and denotes a type (13.10.3).
- The expression `declval<A&>().allocate(size_t{}`). is well-formed when treated as an unevaluated operand.

### 24.2.2.3 Reversible container requirements

A type `X` meets the reversible container requirements if `X` meets the container requirements, the iterator type of `X` belongs to the bidirectional or random access iterator categories (25.3), and the following types and expressions are well-formed and have the specified semantics.

```cpp
typedef X::reverse_iterator
Result: The type `reverse_iterator<X::iterator>`, an iterator type whose value type is `T`.
```

```cpp
typename X::const_reverse_iterator
Result: The type `reverse_iterator<X::const_iterator>`, a constant iterator type whose value type is `T`.
```

```cpp
a.rbegin()
Result: reverse_iterator; const_reverse_iterator for constant `a`.
```

```cpp
Returns: reverse_iterator(end())
Complexity: Constant.
```

```cpp
a.rend()
Result: reverse_iterator; const_reverse_iterator for constant `a`.
```

```cpp
Returns: reverse_iterator(begin())
Complexity: Constant.
```
a.crbegin()

10 Result: const_reverse_iterator.
Returns: const_cast<X const&>(a).rbegin()
Complexity: Constant.

a.crend()

13 Result: const_reverse_iterator.
Returns: const_cast<X const&>(a).rend()
Complexity: Constant.

24.2.2.4 Optional container requirements

The following operations are provided for some types of containers but not others. Those containers for which
the listed operations are provided shall implement the semantics as described unless otherwise stated. If the
iterators passed to lexicographical_compare_three_way meet the constexpr iterator requirements (25.3.1)
then the operations described below are implemented by constexpr functions.

a <=> b

2 Result: synth-three-way-result<X::value_type>.
Preconditions: Either T models three_way_comparable, or < is defined for values of type (possibly
const) T and < is a total ordering relationship.
Returns: lexicographical_compare_three_way(a.begin(), a.end(), b.begin(), b.end(),
synth-three-way)
[Note 1: The algorithm lexicographical_compare_three_way is defined in Clause 27. — end note]
Complexity: Linear.

24.2.2.5 Allocator-aware containers

Except for array, all of the containers defined in Clause 24, 19.6.4, 23.4.3, and 32.9 meet the additional
requirements of an allocator-aware container, as described below.

Given an allocator type A and given a container type X having a value_type identical to T and an allocator_type
identical to allocator_traits<A>::rebind_alloc<T> and given an lvalue m of type A, a pointer p of
type T*, an expression v that denotes an lvalue of type T or const T or an rvalue of type const T, and
an rvalue rv of type T, the following terms are defined. If X is not allocator-aware or is a specialization of
basic_string, the terms below are defined as if A were allocator<T> — no allocator object needs to be
created and user specializations of allocator<T> are not instantiated:

(2.1) — T is Cpp17DefaultInsertable into X means that the following expression is well-formed:
allocator_traits<A>::construct(m, p)

(2.2) — An element of X is default-inserted if it is initialized by evaluation of the expression
allocator_traits<A>::construct(m, p)
where p is the address of the uninitialized storage for the element allocated within X.

(2.3) — T is Cpp17MoveInsertable into X means that the following expression is well-formed:
allocator_traits<A>::construct(m, p, rv)
and its evaluation causes the following postcondition to hold: The value of *p is equivalent to the value
of rv before the evaluation.
[Note 1: rv remains a valid object. Its state is unspecified — end note]

(2.4) — T is Cpp17CopyInsertable into X means that, in addition to T being Cpp17MoveInsertable into X, the
following expression is well-formed:
allocator_traits<A>::construct(m, p, v)
and its evaluation causes the following postcondition to hold: The value of v is unchanged and is
equivalent to *p.

(2.5) — T is Cpp17EmplaceConstructible into X from args, for zero or more arguments args, means that the
following expression is well-formed:
allocator_traits<A>::construct(m, p, args)

(2.6) T is Cpp17Erasable from X means that the following expression is well-formed:

allocator_traits<A>::destroy(m, p)

[Note 2: A container calls allocator_traits<A>::construct(m, p, args) to construct an element at p using args, with m == get_allocator(). The default construct in allocator will call ::new((void*)p) T(args), but specialized allocators can choose a different definition. — end note]

In this subclause,

(3.1) X denotes an allocator-aware container class with a value_type of T using an allocator of type A,

(3.2) u denotes a variable,

(3.3) a and b denote non-const lvalues of type X,

(3.4) c denotes an lvalue of type const X,

(3.5) t denotes an lvalue or a const rvalue of type X,

(3.6) rv denotes a non-const rvalue of type X, and

(3.7) m is a value of type A.

A type X meets the allocator-aware container requirements if X meets the container requirements and the following types, statements, and expressions are well-formed and have the specified semantics.

typename X::allocator_type

Result: A

Mandates: allocator_type::value_type is the same as X::value_type.

c.get_allocator()

Result: A

Complexity: Constant.

X u;
X u = X();

Preconditions: A meets the Cpp17DefaultConstructible requirements.

Postconditions: u.empty() returns true, u.get_allocator() == A().

Complexity: Constant.

X u(m);

Postconditions: u.empty() returns true, u.get_allocator() == m.

Complexity: Constant.

X u(t, m);

Preconditions: T is Cpp17CopyInsertable into X.

Postconditions: u == t, u.get_allocator() == m

Complexity: Linear.

X u(rv);

Postconditions: u has the same elements as rv had before this construction; the value of u.get_allocator() is the same as the value of rv.get_allocator() before this construction.

Complexity: Constant.

X u(rv, m);

Preconditions: T is Cpp17MoveInsertable into X.

Postconditions: u has the same elements, or copies of the elements, that rv had before this construction, u.get_allocator() == m.

Complexity: Constant if m == rv.get_allocator(), otherwise linear.
\[ a = t \]

\textbf{Result:} \( X \).

\textbf{Preconditions:} \( T \) is \texttt{Cpp17CopyInsertable} into \( X \) and \texttt{Cpp17CopyAssignable}.

\textbf{Postconditions:} \( a == t \) is true.

\textbf{Complexity:} Linear.

\[ a = rv \]

\textbf{Result:} \( X \).

\textbf{Preconditions:} If \texttt{allocator_traits<allocator_type>::propagate_on_container_move_assignment::value} is false, \( T \) is \texttt{Cpp17MoveInsertable} into \( X \) and \texttt{Cpp17MoveAssignable}.

\textbf{Effects:} All existing elements of \( a \) are either move assigned to or destroyed.

\textbf{Postconditions:} If \( a \) and \( rv \) do not refer to the same object, \( a \) is equal to the value that \( rv \) had before this assignment.

\textbf{Complexity:} Linear.

\[ a.\text{swap}(b) \]

\textbf{Result:} \texttt{void}

\textbf{Effects:} Exchanges the contents of \( a \) and \( b \).

\textbf{Complexity:} Constant.

### 24.2.4 Sequence containers

\[ \text{sequence.reqmts} \]

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: \texttt{vector}, \texttt{forward_list}, \texttt{list}, and \texttt{deque}. In addition, \texttt{array} is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as stacks, queues, flat maps, flat multimaps, flat sets, or flat multisets, out of the basic sequence container kinds (or out of other program-defined sequence containers).

In this subclause,

\begin{enumerate}
  \item \( X \) denotes a sequence container class,
  \item \( a \) denotes a value of type \( X \) containing elements of type \( T \),
  \item \( u \) denotes the name of a variable being declared,
  \item \( A \) denotes \texttt{X::allocator\_type} if the \texttt{qualified-id X::allocator\_type} is valid and denotes a type \texttt{(13.10.3)} and \texttt{allocator<T>} if it doesn’t,
  \item \( i \) and \( j \) denote iterators that meet the \texttt{Cpp17InputIterator} requirements and refer to elements implicitly convertible to \texttt{value\_type},
  \item \( [i, j) \) denotes a valid range,
  \item \( \text{rg} \) denotes a value of a type \( R \) that models \texttt{container\_compatible\_range<T>},
  \item \( \text{il} \) designates an object of type \texttt{initializer\_list<value\_type>},
  \item \( n \) denotes a value of type \texttt{X::size\_type},
  \item \( p \) denotes a valid constant iterator to \( a \),
\end{enumerate}
--- q denotes a valid dereferenceable constant iterator to a,
--- \([q_1, q_2)\) denotes a valid range of constant iterators in a,
--- t denotes an lvalue or a const rvalue of X::value_type, and
--- rv denotes a non-const rvalue of X::value_type.
--- Args denotes a template parameter pack;
--- args denotes a function parameter pack with the pattern Args&&.

The complexities of the expressions are sequence dependent.

A type X meets the sequence container requirements if X meets the container requirements and the following statements and expressions are well-formed and have the specified semantics.

\[
X u(n, t);
\]
\[\text{Preconditions: } T \text{ is Cpp17CopyInsertable into } X.\]
\[\text{Effects: Constructs a sequence container with } n \text{ copies of } t.\]
\[\text{Postconditions: distance(u.begin(), u.end()) == n is true.}\]

\[
X u(i, j);
\]
\[\text{Preconditions: } T \text{ is Cpp17EmplaceConstructible into } X \text{ from *i. For vector, if the iterator does not meet the Cpp17ForwardIterator requirements (25.3.5.5), } T \text{ is also Cpp17MoveInsertable into } X.\]
\[\text{Effects: Constructs a sequence container equal to the range } [i, j). \text{ Each iterator in the range } [i,j) \text{ is dereferenced exactly once.}\]
\[\text{Postconditions: distance(u.begin(), u.end()) == distance(i, j) is true.}\]

\[
X(\text{from range, rg})
\]
\[\text{Preconditions: } T \text{ is Cpp17EmplaceConstructible into } X \text{ from *ranges::begin(rg). For vector, if R models neither ranges::sized_range nor ranges::forward_range, } T \text{ is also Cpp17MoveInsertable into } X.\]
\[\text{Effects: Constructs a sequence container equal to the range } \text{rg}. \text{ Each iterator in the range } \text{rg} \text{ is dereferenced exactly once.}\]
\[\text{Postconditions: distance(begin(), end()) == ranges::distance(rg) is true.}\]

\[
X(il)
\]
\[\text{Effects: Equivalent to } X(il.\text{begin()}, il.\text{end()}).\]

\[
a = il
\]
\[\text{Result: } X\&.\]
\[\text{Preconditions: } T \text{ is Cpp17CopyInsertable into } X \text{ and Cpp17CopyAssignable.}\]
\[\text{Effects: Assigns the range } [il.\text{begin()},il.\text{end()}) \text{ into } a. \text{ All existing elements of } a \text{ are either assigned to or destroyed.}\]
\[\text{Returns: } *\text{this}.\]

\[
a.\text{emplace}(p, \text{args})
\]
\[\text{Result: } \text{iterator.}\]
\[\text{Preconditions: } T \text{ is Cpp17EmplaceConstructible into } X \text{ from args. For vector and deque, } T \text{ is also Cpp17MoveInsertable into } X \text{ and Cpp17MoveAssigneable.}\]
\[\text{Effects: Inserts an object of type } T \text{ constructed with std::forward<Args>(args)... before } p.\]
[Note 1: args can directly or indirectly refer to a value in a. — end note]
\[\text{Returns: } \text{An iterator that points to the new element constructed from args into } a.\]

\[
a.\text{insert}(p, t)
\]
\[\text{Result: } \text{iterator}.\]
\[\text{Preconditions: } T \text{ is Cpp17CopyInsertable into } X. \text{ For vector and deque, } T \text{ is also Cpp17CopyAssigneable.}\]
Effects: Inserts a copy of \( t \) before \( p \).

Returns: An iterator that points to the copy of \( t \) inserted into \( a \).

\[
a \text{.insert}(p, rv)
\]

Result: iterator.

 Preconditions: \( T \) is Cpp17MoveInsertable into \( X \). For \texttt{vector} and \texttt{deque}, \( T \) is also Cpp17MoveAssignable.

 Effects: Inserts a copy of \( rv \) before \( p \).

 Returns: An iterator that points to the copy of \( rv \) inserted into \( a \).

\[
a \text{.insert}(p, n, t)
\]

Result: iterator.

 Preconditions: \( T \) is Cpp17CopyInsertable into \( X \) and Cpp17CopyAssignable.

 Effects: Inserts \( n \) copies of \( t \) before \( p \).

 Returns: An iterator that points to the copy of the first element inserted into \( a \), or \( p \) if \( n == 0 \).

\[
a \text{.insert}(p, i, j)
\]

Result: iterator.

 Preconditions: \( T \) is Cpp17EmplaceConstructible into \( X \) from \(*i\). For \texttt{vector} and \texttt{deque}, \( T \) is also Cpp17MoveInsertable into \( X \), and \( T \) meets the Cpp17MoveConstructible, Cpp17MoveAssignable, and Cpp17Swappable (16.4.4.3) requirements. Neither \( i \) nor \( j \) are iterators into \( a \).

 Effects: Inserts copies of elements in \([i, j)\) before \( p \). Each iterator in the range \([i, j)\) shall be dereferenced exactly once.

 Returns: An iterator that points to the copy of the first element inserted into \( a \), or \( p \) if \( i == j \).

\[
a \text{.insert_range}(p, rg)
\]

Result: iterator.

 Preconditions: \( T \) is Cpp17EmplaceConstructible into \( X \) from \(*\text{ranges::begin}(rg)\). For \texttt{vector} and \texttt{deque}, \( T \) is also Cpp17MoveInsertable into \( X \), and \( T \) meets the Cpp17MoveConstructible, Cpp17MoveAssignable, and Cpp17Swappable (16.4.4.3) requirements. \( rg \) and \( a \) do not overlap.

 Effects: Inserts copies of elements in \( rg \) before \( p \). Each iterator in the range \( rg \) is dereferenced exactly once.

 Returns: An iterator that points to the copy of the first element inserted into \( a \), or \( p \) if \( rg \) is empty.

\[
a \text{.insert}(p, il)
\]

 Effects: Equivalent to \( a \text{.insert}(p, il\text{.begin()}, il\text{.end()}) \).

\[
a \text{.erase}(q)
\]

Result: iterator.

 Preconditions: For \texttt{vector} and \texttt{deque}, \( T \) is Cpp17MoveAssignable.

 Effects: Erases the element pointed to by \( q \).

 Returns: An iterator that points to the element immediately following \( q \) prior to the element being erased. If no such element exists, \( a\text{.end()} \) is returned.

\[
a \text{.erase}(q1, q2)
\]

Result: iterator.

 Preconditions: For \texttt{vector} and \texttt{deque}, \( T \) is Cpp17MoveAssignable.

 Effects: Erases the elements in the range \([q1, q2)\).

 Returns: An iterator that points to the element pointed to by \( q2 \) prior to any elements being erased. If no such element exists, \( a\text{.end()} \) is returned.

\[
a \text{.clear()}
\]

 Result: void
53 Effects: Destroys all elements in a. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

54 Postconditions: a.empty() is true.

55 Complexity: Linear.

56 a.assign(i, j)

57 Result: void

58 Preconditions: T is Cpp17EmplaceConstructible into X from *i and assignable from *i. For vector, if the iterator does not meet the forward iterator requirements (25.3.5.5), T is also Cpp17MoveInsertable into X. Neither i nor j are iterators into a.

59 Effects: Replaces elements in a with a copy of [i, j). Invalidates all references, pointers and iterators referring to the elements of a. For vector and deque, also invalidates the past-the-end iterator. Each iterator in the range [i, j) is dereferenced exactly once.

59 a.assign_range(rg)

60 Result: void

61 Mandates: assignable_from<T&, ranges::range_reference_t<R>> is modeled.

62 Preconditions: T is Cpp17EmplaceConstructible into X from *ranges::begin(rg). For vector, if R models neither ranges::sized_range nor ranges::forward_range, T is also Cpp17MoveInsertable into X. rg and a do not overlap.

63 Effects: Replaces elements in a with a copy of each element in rg. Invalidates all references, pointers, and iterators referring to the elements of a. For vector and deque, also invalidates the past-the-end iterator. Each iterator in the range rg is dereferenced exactly once.

63 a.assign(il)

64 Effects: Equivalent to a.assign(il.begin(), il.end()).

64 a.assign(n, t)

65 Result: void

66 Preconditions: T is Cpp17CopyInsertable into X and Cpp17CopyAssignable. t is not a reference into a.

67 Effects: Replaces elements in a with n copies of t. Invalidates all references, pointers and iterators referring to the elements of a. For vector and deque, also invalidates the past-the-end iterator.

67 For every sequence container defined in this Clause and in Clause 23:

(67.1) — If the constructor

```cpp
template<class InputIterator>
X(InputIterator first, InputIterator last,
const allocator_type& alloc = allocator_type());
```

is called with a type InputIterator that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

(67.2) — If the member functions of the forms:

```cpp
template<class InputIterator>
return-type F(const_iterator p,
InputIterator first, InputIterator last); // such as insert
```

```cpp
template<class InputIterator>
return-type F(InputIterator first, InputIterator last); // such as append, assign
```

```cpp
template<class InputIterator>
return-type F(const_iterator i1, const_iterator i2,
InputIterator first, InputIterator last); // such as replace
```

are called with a type InputIterator that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

(67.3) — A deduction guide for a sequence container shall not participate in overload resolution if it has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced
for that parameter, or if it has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

The following operations are provided for some types of sequence containers but not others. Operations other than prepend_range and append_range are implemented so as to take amortized constant time.

\[ \text{a.front()} \]

\textbf{Result}: reference; const reference for constant a.

\textbf{Returns}: *a.begin()

\textbf{Remarks}: Required for basic_string, array, deque, forward_list, list, and vector.

\[ \text{a.back()} \]

\textbf{Result}: reference; const reference for constant a.

\textbf{Effects}: Equivalent to:
\begin{verbatim}
auto tmp = a.end();
--tmp;
return *tmp;
\end{verbatim}

\textbf{Remarks}: Required for basic_string, array, deque, list, and vector.

\[ \text{a.emplace_front(args)} \]

\textbf{Result}: reference

\textbf{Preconditions}: T is Cpp17EmplaceConstructible into X from args.

\textbf{Effects}: Prepends an object of type T constructed with std::forward<Args>(args)...

\textbf{Returns}: a.front().

\textbf{Remarks}: Required for deque, forward_list, and list.

\[ \text{a.emplace_back(args)} \]

\textbf{Result}: reference

\textbf{Preconditions}: T is Cpp17EmplaceConstructible into X from args. For vector, T is also Cpp17MoveInsertable into X.

\textbf{Effects}: Appends an object of type T constructed with std::forward<Args>(args)...

\textbf{Returns}: a.back().

\textbf{Remarks}: Required for deque, list, and vector.

\[ \text{a.push_front(t)} \]

\textbf{Result}: void

\textbf{Preconditions}: T is Cpp17CopyInsertable into X.

\textbf{Effects}: Prepends a copy of t.

\textbf{Remarks}: Required for deque, forward_list, and list.

\[ \text{a.push_front(rv)} \]

\textbf{Result}: void

\textbf{Preconditions}: T is Cpp17MoveInsertable into X.

\textbf{Effects}: Prepends a copy of rv.

\textbf{Remarks}: Required for deque, forward_list, and list.

\[ \text{a.prepend_range(rg)} \]

\textbf{Result}: void

\textbf{Preconditions}: T is Cpp17EmplaceConstructible into X from *ranges::begin(rg). For deque, T is also Cpp17MoveInsertable into X, and T meets the Cpp17MoveConstructible, Cpp17MoveAssignable, and Cpp17Swappable (16.4.4.3) requirements.
Effects: Inserts copies of elements in \( \mathbf{rg} \) before \begin{function}\end{function}. Each iterator in the range \( \mathbf{rg} \) is dereferenced exactly once.

[Note 2: The order of elements in \( \mathbf{rg} \) is not reversed. — end note]

Remarks: Required for \texttt{deque}, \texttt{forward\_list}, and \texttt{list}.

\begin{function}{\texttt{a.push\_back}}(t)\end{function}

Result: void

Preconditions: \( T \) is \texttt{Cpp17Copyinsertable} into \( \mathbf{X} \).

Effects: Appends a copy of \( t \).

Remarks: Required for \texttt{basic\_string}, \texttt{deque}, \texttt{list}, and \texttt{vector}.

\begin{function}{\texttt{a.push\_back}}(rv)\end{function}

Result: void

Preconditions: \( T \) is \texttt{Cpp17Moveinsertable} into \( \mathbf{X} \).

Effects: Appends a copy of \( rv \).

Remarks: Required for \texttt{basic\_string}, \texttt{deque}, \texttt{list}, and \texttt{vector}.

\begin{function}{\texttt{a.append\_range}}(rg)\end{function}

Result: void

Preconditions: \( T \) is \texttt{Cpp17Emplaceconstructible} into \( \mathbf{X} \) from \texttt{\*ranges::begin}(rg). For \texttt{vector}, \( T \) is also \texttt{Cpp17Moveinsertable} into \( \mathbf{X} \).

Effects: Inserts copies of elements in \( \mathbf{rg} \) before \texttt{end}(). Each iterator in the range \( \mathbf{rg} \) is dereferenced exactly once.

Remarks: Required for \texttt{deque}, \texttt{list}, and \texttt{vector}.

\begin{function}{\texttt{a.pop\_front}}()\end{function}

Result: void

Preconditions: \( \texttt{a.empty}() \) is \texttt{false}.

Effects: Destroys the first element.

Remarks: Required for \texttt{deque}, \texttt{forward\_list}, and \texttt{list}.

\begin{function}{\texttt{a.pop\_back}}()\end{function}

Result: void

Preconditions: \( \texttt{a.empty}() \) is \texttt{false}.

Effects: Destroys the last element.

Remarks: Required for \texttt{basic\_string}, \texttt{deque}, \texttt{list}, and \texttt{vector}.

\begin{function}{a[n]}\end{function}

Result: reference; \texttt{const\_reference} for constant \( a \)

Effects: Equivalent to: \texttt{return \*a.begin() + n};

Remarks: Required for \texttt{basic\_string}, \texttt{array}, \texttt{deque}, and \texttt{vector}.

\begin{function}{\texttt{a.at}(n)}\end{function}

Result: reference; \texttt{const\_reference} for constant \( a \)

Returns: \texttt{\*a.begin() + n}

Throws: \texttt{out\_of\_range} if \( n \geq a\text{\_size}() \).

Remarks: Required for \texttt{basic\_string}, \texttt{array}, \texttt{deque}, and \texttt{vector}.
24.2.5 Node handles

24.2.5.1 Overview

A node handle is an object that accepts ownership of a single element from an associative container (24.2.7) or an unordered associative container (24.2.8). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 83.

Table 83 — Container types with compatible nodes

</tbody>
</table>

If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

Class node-handle is for exposition only.

If a user-defined specialization of pair exists for pair<const Key, T> or pair<Key, T>, where Key is the container’s key_type and T is the container’s mapped_type, the behavior of operations involving node handles is undefined.

```cpp
template<unspecified>
class node-handle {

public:
    // These type declarations are described in 24.2.7 and 24.2.8.
    using value_type = see below; // not present for map containers
    using key_type = see below; // not present for set containers
    using mapped_type = see below; // not present for set containers
    using allocator_type = see below;

private:
    using container_node_type = unspecified; // exposition only
    using ator_traits = allocator_traits<allocator_type>; // exposition only

    typename ator_traits::template rebind_traits<container_node_type>::pointer ptr_; // exposition only
    optional<allocator_type> alloc_; // exposition only

public:
    // 24.2.5.2, constructors, copy, and assignment
    constexpr node-handle() noexcept : ptr_(), alloc_() {}
    node-handle(node-handle&&) noexcept;
    node-handle& operator=(node-handle&&);

    // 24.2.5.3, destructor
    ~node-handle();

    // 24.2.5.4, observers
    value_type& value() const; // not present for map containers
    key_type& key() const; // not present for set containers
    mapped_type& mapped() const; // not present for set containers

    allocator_type get_allocator() const;
    explicit operator bool() const noexcept;
    [[nodiscard]] bool empty() const noexcept;
};
```
void swap(node-handle&)
    noexcept(ator_traits::propagate_on_container_swap::value ||
        ator_traits::is_always_equal::value);

friend void swap(node-handle x, node-handle y) noexcept(noexcept(x.swap(y))) {
    x.swap(y);
}

24.2.5.2 Constructors, copy, and assignment
    [container.node.cons]

node-handle(node-handle&& nh) noexcept;

    Effects: Constructs a node-handle object initializing ptr_ with nh.ptr_. Move constructs alloc_ with nh.alloc_. Assigns nullptr to nh.ptr and assigns nullopt to nh.alloc_.

node-handle& operator=(node-handle&& nh);

    Preconditions: Either !alloc_, or ator_traits::propagate_on_container_move_assignment::value is true, or alloc_ == nh.alloc_.

    Effects:
    (3.1) — If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.
    (3.2) — Assigns nh.ptr_ to ptr_.
    (3.3) — If !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, move assigns nh.alloc_ to alloc_.
    (3.4) — Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

    Returns: *this.

    Throws: Nothing.

24.2.5.3 Destructor
    [container.node.dtor]

~node-handle();

    Effects: If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.

24.2.5.4 Observers
    [container.node.observers]

value_type& value() const;

    Preconditions: empty() == false.

    Returns: A reference to the value_type subobject in the container_node_type object pointed to by ptr_.

    Throws: Nothing.

key_type& key() const;

    Preconditions: empty() == false.

    Returns: A non-const reference to the key_type member of the value_type subobject in the container_node_type object pointed to by ptr_.

    Throws: Nothing.

Remarks: Modifying the key through the returned reference is permitted.

mapped_type& mapped() const;

    Preconditions: empty() == false.

    Returns: A reference to the mapped_type member of the value_type subobject in the container_node_type object pointed to by ptr_.
10   Throws: Nothing.

   allocator_type get_allocator() const;
11   
12   Preconditions: empty() == false.
13   
14   Returns: *alloc_.
15   
16   Throws: Nothing.
17   
18   explicit operator bool() const noexcept;
19   
20   Returns: ptr_ != nullptr.
21   
22   [nodiscard] bool empty() const noexcept;
23   
24   Returns: ptr_ == nullptr.
25
24.2.5.5 Modifiers

24.2.6 Insert return type

24.2.7 Associative containers

24.2.7.1 General

Each associative container is parameterized on Key and an ordering relation Compare that induces a strict weak ordering (27.8) on elements of Key. In addition, map and multimap associate an arbitrary mapped type T with the Key. The object of type Compare is called the comparison object of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That is, two keys k1 and k2 are considered to be equivalent if for the comparison object \( \text{comp} \), \( \text{comp}(k1, k2) == false \) & \( \text{comp}(k2, k1) == false \).

\[ \text{Note 1: This is not necessarily the same as the result of } k1 == k2. \] — end note

For any two keys k1 and k2 in the same container, calling \( \text{comp}(k1, k2) \) shall always return the same value.

An associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. The set and map classes support unique keys; the multiset and multimap
classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

5 For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[Note 2: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note]

7 In this subclause,

- `X` denotes an associative container class,
- `a` denotes a value of type `X`,
- `a2` denotes a value of a type with nodes compatible with type `X` (Table 83),
- `b` denotes a value or type `X` or `const X`,
- `u` denotes the name of a variable being declared,
- `a_uniq` denotes a value of type `X` when `X` supports unique keys,
- `a_eq` denotes a value of type `X` when `X` supports multiple keys,
- `a_tran` denotes a value of type `X` or `const X` when the qualified-id `X::key_compare::is_transparent` is valid and denotes a type (13.10.3),
- `i` and `j` meet the `Cpp17InputIterator` requirements and refer to elements implicitly convertible to `value_type`,
- `[i, j)` denotes a valid range,
- `rg` denotes a value of a type `R` that models `container-compatible-range<value_type>`,
- `p` denotes a valid constant iterator to `a`,
- `q` denotes a valid dereferenceable constant iterator to `a`,
- `r` denotes a valid dereferenceable iterator to `a`,
- `[q1, q2)` denotes a valid range of constant iterators in `a`,
- `il` designates an object of type `initializer_list<value_type>`,
- `t` denotes a value of type `X::value_type`,
- `k` denotes a value of type `X::key_type`, and
- `c` denotes a value of type `X::key_compare` or `const X::key_compare`;
- `kl` is a value such that `a` is partitioned (27.8) with respect to `c(x, kl)`, with `x` the key value of `e` and `e` in `a`;
- `ku` is a value such that `a` is partitioned with respect to `!c(ku, x)`, with `x` the key value of `e` and `e` in `a`;
- `ke` is a value such that `a` is partitioned with respect to `c(x, ke)` and `!c(ke, x)`, with `c(x, ke)` implying `!c(ke, x)` and with `x` the key value of `e` and `e` in `a`;
- `kx` is a value such that
  - `a` is partitioned with respect to `c(x, kx)` and `!c(kx, x)`, with `c(x, kx)` implying `!c(kx, x)` and with `x` the key value of `e` and `e` in `a`, and
  - `kx` is not convertible to either `iterator` or `const_iterator`; and
- `A` denotes the storage allocator used by `X`, if any, or `allocator<X::value_type>` otherwise,
- `m` denotes an allocator of a type convertible to `A`, and `nh` denotes a non-const rvalue of type `X::node_type`;

8 A type `X` meets the `associative container` requirements if `X` meets all the requirements of an allocator-aware container (24.2.2.2) and the following types, statements, and expressions are well-formed and have the
specified semantics, except that for map and multimap, the requirements placed on value_type in 24.2.2.5 apply instead to key_type and mapped_type.

[Note 3: For example, in some cases key_type and mapped_type are required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

```cpp
typedef X::key_type
  Result: Key.
typedef X::mapped_type
  Result: T.
  Remarks: For map and multimap only.
typedef X::value_type
  Result: Key for set and multiset only; pair<const Key, T> for map and multimap only.
  Preconditions: X::value_type is Cpp17Erasable from X.
typedef X::key_compare
  Result: Compare.
  Preconditions: key_compare is Cpp17CopyConstructible.
typedef X::value_compare
  Result: A binary predicate type. It is the same as key_compare for set and multiset; is an ordering relation on pairs induced by the first component (i.e., Key) for map and multimap.
typedef X::node_type
  Result: A specialization of the node-handle class template (24.2.5), such that the public nested types are the same types as the corresponding types in X.
```

```cpp
X(c)
  Effects: Constructs an empty container. Uses a copy of c as a comparison object.
  Complexity: Constant.
X u = X();
X u;
  Preconditions: key_compare meets the Cpp17DefaultConstructible requirements.
  Effects: Constructs an empty container. Uses Compare() as a comparison object.
  Complexity: Constant.

X(i, j, c)
  Preconditions: value_type is Cpp17EmplaceConstructible into X from *i.
  Effects: Constructs an empty container and inserts elements from the range [i, j) into it; uses c as a comparison object.
  Complexity: N log N in general, where N has the value distance(i, j); linear if [i, j) is sorted with respect to value_comp().

X(i, j)
  Preconditions: key_compare meets the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into X from *i.
  Effects: Constructs an empty container and inserts elements from the range [i, j) into it; uses Compare() as a comparison object.
  Complexity: N log N in general, where N has the value distance(i, j); linear if [i, j) is sorted with respect to value_comp().

X(from_range, rg, c)
  Preconditions: value_type is Cpp17EmplaceConstructible into X from *ranges::begin(rg).
```
Effects: Constructs an empty container and inserts each element from \(rg\) into it. Uses \(c\) as the comparison object.

Complexity: \(N \log N\) in general, where \(N\) has the value \(\text{ranges::distance}(rg)\); linear if \(rg\) is sorted with respect to \(\text{value\_comp}\).

\[X(\text{from\_range}, \, rg)\]

Preconditions: \(\text{key\_compare}\) meets the \(\text{Cpp17DefaultConstructible}\) requirements. \(\text{value\_type}\) is \(\text{Cpp17EmplaceConstructible}\) into \(X\) from \(*\text{ranges::begin}(rg)\).

Effects: Constructs an empty container and inserts each element from \(rg\) into it. Uses \(\text{Compare}\) as the comparison object.

Complexity: Same as \(X(\text{from\_range}, \, rg, \, c)\).

\[X(\text{il}, \, c)\]

Effects: Equivalent to \(X(\text{il.begin()}, \, \text{il.end()}, \, c)\).

\[X(\text{il})\]

Effects: Equivalent to \(X(\text{il.begin()}, \, \text{il.end})\).

\[\text{a} = \text{il}\]

Result: \(X\&\)

Preconditions: \(\text{value\_type}\) is \(\text{Cpp17CopyInsertable}\) into \(X\) and \(\text{Cpp17CopyAssignble}\).

Effects: Assigns the range \([\text{il.begin()}, \, \text{il.end()}]\) into \(a\). All existing elements of \(a\) are either assigned to or destroyed.

Complexity: \(N \log N\) in general, where \(N\) has the value \(\text{il.size()} + a]\).size(); linear if \([\text{il.begin()}, \, \text{il.end()}]\) is sorted with respect to \(\text{value\_comp}\).

\(b\).key\_comp()

Result: \(X::\text{key\_compare}\)

Returns: The comparison object out of which \(b\) was constructed.

Complexity: Constant.

\(b\).value\_comp()

Result: \(X::\text{value\_compare}\)

Returns: An object of \(\text{value\_compare}\) constructed out of the comparison object.

Complexity: Constant.

\(a\_uniq\).emplace(args)

Result: \(\text{pair<iterator, \, bool>}\)

Preconditions: \(\text{value\_type}\) is \(\text{Cpp17EmplaceConstructible}\) into \(X\) from \(args\).

Effects: Inserts a \(\text{value\_type}\) object \(t\) constructed with \(\text{std::forward<Args>(args)}\) if and only if there is no element in the container with key equivalent to the key of \(t\).

Returns: The \(\text{bool}\) component of the returned pair is \(\text{true}\) if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of \(t\).

Complexity: Logarithmic.

\(a\_eq\).emplace(args)

Result: \(\text{iterator}\)

Preconditions: \(\text{value\_type}\) is \(\text{Cpp17EmplaceConstructible}\) into \(X\) from \(args\).

Effects: Inserts a \(\text{value\_type}\) object \(t\) constructed with \(\text{std::forward<Args>(args)}\). If a range containing elements equivalent to \(t\) exists in \(a\_eq\), \(t\) is inserted at the end of that range.

Returns: An iterator pointing to the newly inserted element.

Complexity: Logarithmic.
a.emplace_hint(p, args)

Result: iterator

Effects: Equivalent to `a.emplace(std::forward<Args>(args)...), except that the element is inserted as close as possible to the position just prior to p.

Returns: An iterator pointing to the element with the key equivalent to the newly inserted element.

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before p.

a_uniq.insert(t)

Result: pair<iterator, bool>

Preconditions: If t is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into X; otherwise, `value_type` is `Cpp17CopyInsertable` into X.

Effects: Inserts t if and only if there is no element in the container with key equivalent to the key of t.

Returns: The bool component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of t.

Complexity: Logarithmic.

a_eq.insert(t)

Result: iterator

Preconditions: If t is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into X; otherwise, `value_type` is `Cpp17CopyInsertable` into X.

Effects: Inserts t and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to t exists in a_eq, t is inserted at the end of that range.

Complexity: Logarithmic.

a.insert(p, t)

Result: iterator

Preconditions: If t is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into X; otherwise, `value_type` is `Cpp17CopyInsertable` into X.

Effects: Inserts t if and only if there is no element with key equivalent to the key of t in containers with unique keys; always inserts t in containers with equivalent keys. t is inserted as close as possible to the position just prior to p.

Returns: An iterator pointing to the element with key equivalent to the key of t.

Complexity: Logarithmic in general, but amortized constant if t is inserted right before p.

a.insert(i, j)

Result: void

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into X from *i. Neither i nor j are iterators into a.

Effects: Inserts each element from the range [i, j) if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: $N \log(a.size() + N)$, where N has the value `distance(i, j).

a.insert_range(rg)

Result: void

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into X from *ranges::begin(rg). rg and a do not overlap.

Effects: Inserts each element from rg if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: $N \log(a.size() + N)$, where N has the value ranges::distance(rg).
a.insert(il)

Effects: Equivalent to a.insert(il.begin(), il.end()).

a_uniq.insert(nh)

Result: insert_return_type

Preconditions: nh is empty or a_uniq.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect. Otherwise, inserts the element owned by nh if and only if there is no element in the container with a key equivalent to nh.key().

Returns: If nh is empty, inserted is false, position is end(), and node is empty. Otherwise if the insertion took place, inserted is true, position points to the inserted element, and node is empty; if the insertion failed, inserted is false, node has the previous value of nh, and position points to an element with a key equivalent to nh.key().

Complexity: Logarithmic.

a_eq.insert(nh)

Result: iterator

Preconditions: nh is empty or a_eq.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect and returns a_eq.end(). Otherwise, inserts the element owned by nh and returns an iterator pointing to the newly inserted element. If a range containing elements with keys equivalent to nh.key() exists in a_eq, the element is inserted at the end of that range.

Postconditions: nh is empty.

Complexity: Logarithmic.

a.insert(p, nh)

Result: iterator

Preconditions: nh is empty or a.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect and returns a.end(). Otherwise, inserts the element owned by nh if and only if there is no element with key equivalent to nh.key() in containers with unique keys; always inserts the element owned by nh in containers with equivalent keys. The element is inserted as close as possible to the position just prior to p.

Postconditions: nh is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to nh.key().

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before p.

a.extract(k)

Result: node_type

Effects: Removes the first element in the container with key equivalent to k.

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: log(a.size())

a_tran.extract(kx)

Result: node_type

Effects: Removes the first element in the container with key r such that !c(r, kx) && !c(kx, r) is true.

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: log(a_tran.size())

a.extract(q)

Result: node_type

Effects: Removes the element pointed to by q.

Returns: A node_type owning that element.
Complexity: Amortized constant.

\begin{verbatim}
a.merge(a2)
\end{verbatim}

**Result**: void

**Preconditions**: \( a.\text{get}\_\text{allocator}() == a2.\text{get}\_\text{allocator}() \).

**Effects**: Attempts to extract each element in \( a2 \) and insert it into \( a \) using the comparison object of \( a \). In containers with unique keys, if there is an element in \( a \) with key equivalent to the key of an element from \( a2 \), then that element is not extracted from \( a2 \).

**Postconditions**: Pointers and references to the transferred elements of \( a2 \) refer to those same elements but as members of \( a \). Iterators referring to the transferred elements will continue to refer to their elements, but they now behave as iterators into \( a \), not into \( a2 \).

**Throws**: Nothing unless the comparison object throws.

**Complexity**: \( N \log(a.\text{size}()+N) \), where \( N \) has the value \( a2.\text{size}() \).

\begin{verbatim}
a.erase(k)
\end{verbatim}

**Result**: size_type

**Effects**: Erases all elements in the container with key equivalent to \( k \).

**Returns**: The number of erased elements.

**Complexity**: \( \log(a.\text{size}()) + a.\text{count}(k) \)

\begin{verbatim}
a_tran.erase(kx)
\end{verbatim}

**Result**: size_type

**Effects**: Erases all elements in the container with key \( r \) such that \( !c(r, kx) \&\& !c(kx, r) \) is true.

**Returns**: The number of erased elements.

**Complexity**: \( \log(a\_\text{tran}.\text{size}()) + a\_\text{tran}.\text{count}(kx) \)

\begin{verbatim}
a.erase(q)
\end{verbatim}

**Result**: iterator

**Effects**: Erases the element pointed to by \( q \).

**Returns**: An iterator pointing to the element immediately following \( q \) prior to the element being erased. If no such element exists, returns \( a.\text{end}() \).

**Complexity**: Amortized constant.

\begin{verbatim}
a.erase(r)
\end{verbatim}

**Result**: iterator

**Effects**: Erases the element pointed to by \( r \).

**Returns**: An iterator pointing to the element immediately following \( r \) prior to the element being erased. If no such element exists, returns \( a.\text{end}() \).

**Complexity**: Amortized constant.

\begin{verbatim}
a.erase(q1, q2)
\end{verbatim}

**Result**: iterator

**Effects**: Erases all the elements in the range \([q1, q2)\).

**Returns**: An iterator pointing to the element pointed to by \( q2 \) prior to any elements being erased. If no such element exists, \( a.\text{end}() \) is returned.

**Complexity**: \( \log(a.\text{size}()) + N \), where \( N \) has the value \( \text{distance}(q1, q2) \).

\begin{verbatim}
a.clear()
\end{verbatim}

**Effects**: Equivalent to \( a.\text{erase}(a.\text{begin}(), a.\text{end}()) \).

**Postconditions**: \( a.\text{empty}() \) is true.

**Complexity**: Linear in \( a.\text{size}() \).
b.find(k)
  \textit{Result: iterator; const\_iterator for constant b.}
  Returns: An iterator pointing to an element with the key equivalent to k, or b.end() if such an element
  is not found.
  \textit{Complexity: Logarithmic.}

a_tran.find(ke)
  \textit{Result: iterator; const\_iterator for constant a\_tran.}
  Returns: An iterator pointing to an element with key r such that !c(r, ke) && !c(ke, r) is true, or
  a\_tran.end() if such an element is not found.
  \textit{Complexity: Logarithmic.}

b.count(k)
  \textit{Result: size\_type}
  Returns: The number of elements with key equivalent to k.
  \textit{Complexity: log(b.size()) + b.count(k)}

a_tran.count(ke)
  \textit{Result: size\_type}
  Returns: The number of elements with key r such that !c(r, ke) && c(ke, r).
  \textit{Complexity: log(a\_tran.size()) + a\_tran.count(ke)}

b.contains(k)
  \textit{Result: bool}
  Effects: Equivalent to: return b.find(k) != b.end();

a_tran.contains(ke)
  \textit{Result: bool}
  Effects: Equivalent to: return a\_tran.find(ke) != a\_tran.end();

b.lower_bound(k)
  \textit{Result: iterator; const\_iterator for constant b.}
  \textit{Returns:} An iterator pointing to the first element with key not less than k, or b.end() if such an
  element is not found.
  \textit{Complexity: Logarithmic.}

a_tran.lower_bound(kl)
  \textit{Result: iterator; const\_iterator for constant a\_tran.}
  \textit{Returns:} An iterator pointing to the first element with key r such that !c(r, kl), or a\_tran.end() if
  such an element is not found.
  \textit{Complexity: Logarithmic.}

b.upper_bound(k)
  \textit{Result: iterator; const\_iterator for constant b.}
  \textit{Returns:} An iterator pointing to the first element with key greater than k, or b.end() if such an
  element is not found.
  \textit{Complexity: Logarithmic.}

a_tran.upper_bound(ku)
  \textit{Result: iterator; const\_iterator for constant a\_tran.}
  \textit{Returns:} An iterator pointing to the first element with key r such that c(ku, r), or a\_tran.end() if
  such an element is not found.
Complexity: Logarithmic.

\[ b.\text{equal\_range}(k) \]

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant b.

Effects: Equivalent to: return make_pair(b.lower_bound(k), b.upper_bound(k));

Complexity: Logarithmic.

\[ a\text{_tran}.\text{equal\_range}(ke) \]

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant a_tran.

Effects: Equivalent to: return make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke));

Complexity: Logarithmic.

The insert, insert_range, and emplace members shall not affect the validity of iterators and references to the container, and the erase members shall invalidate only iterators and references to the erased elements.

The extract members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators \( i \) and \( j \) such that distance from \( i \) to \( j \) is positive, the following condition holds:

\[ \text{value\_comp}(\*j, \*i) = \text{false} \]

For associative containers with unique keys the stronger condition holds:

\[ \text{value\_comp}(\*i, \*j) != \text{false} \]

When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

The member function templates find, count, contains, lower_bound, upper_bound, equal_range, erase, and extract shall not participate in overload resolution unless the qualified-id Compare::is\_transparent is valid and denotes a type (13.10.3). Additionally, the member function templates extract and erase shall not participate in overload resolution if is\_convertible_v<K&&, iterator> || is\_convertible_v<K&&, const_iterator> is true, where \( K \) is the type substituted as the first template argument.

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

(181.1) — It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(181.2) — It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(181.3) — It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 24.2.7.2 Exception safety guarantees [associative.reqmts.except]

1. For associative containers, no clear() function throws an exception. erase(k) does not throw an exception unless that exception is thrown by the container’s Compare object (if any).

2. For associative containers, if an exception is thrown by any operation from within an insert or emplace function inserting a single element, the insertion has no effect.

3. For associative containers, no swap function throws an exception unless that exception is thrown by the swap of the container’s Compare object (if any).
24.2.8 Unordered associative containers

24.2.8.1 General

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

2 Unordered associative containers conform to the requirements for Containers (24.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

3 Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the Cpp17Hash requirements (16.4.4.5) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary mapped type `T` with the `Key`.

4 The container’s object of type `Hash` — denoted by `hash` — is called the hash function of the container. The container’s object of type `Pred` — denoted by `pred` — is called the key equality predicate of the container.

5 Two values `k1` and `k2` are considered equivalent if the container’s key equality predicate `pred(k1, k2)` is valid and returns `true` when passed those values. If `k1` and `k2` are equivalent, the container’s hash function shall return the same value for both.

[Note 1: Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — end note] For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

6 An unordered associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into equivalent-key groups such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

7 For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `pair<const Key, T>`.

8 For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[Note 2: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note] The elements of an unordered associative container are organized into buckets. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.

In this subclause,

1. `X` denotes an unordered associative container class,
2. `a` denotes a value of type `X`,
3. `a2` denotes a value of a type with nodes compatible with type `X` (Table 83),
4. `b` denotes a value of type `X` or `const X`,
5. `a_uniq` denotes a value of type `X` when `X` supports unique keys,
6. `a_eq` denotes a value of type `X` when `X` supports equivalent keys,
7. `a_tran` denotes a value of type `X` or `const X` when the qualified-ids `X::key_equal::is_transparent` and `X::hasher::is_transparent` are both valid and denote types (13.10.3).
A type `X` meets the unordered associative container requirements if `X` meets all the requirements of an allocator-aware container (24.2.2.2) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for `unordered_map` and `unordered_multimap`, the requirements placed on `value_type` in 24.2.2.5 apply instead to `key_type` and `mapped_type`.

[Note 3: For example, `key_type` and `mapped_type` are sometimes required to be `Cpp17CopyAssignable` even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not `Cpp17CopyAssignable`. — end note]

typename `X::key_type`

Result: Key.

typename `X::mapped_type`

Result: T.

Remarks: For unordered_map and unordered_multimap only.

typename `X::value_type`

Result: Key for unordered_set and unordered_multiset only; `pair<const Key, T>` for unordered_map and unordered_multimap only.

Preconditions: `value_type` is `Cpp17Erasable` from `X`.

typename `X::hasher`

Result: Hash.

Preconditions: Hash is a unary function object type such that the expression `hf(k)` has type `size_t`. 

§ 24.2.8.1
**typename X::key_equal**

*Result:* Pred.

*Preconditions:* Pred meets the Cpp17CopyConstructible requirements. Pred is a binary predicate that takes two arguments of type Key. Pred is an equivalence relation.

**typename X::local_iterator**

*Result:* An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::iterator’s.

[Note 4: A local_iterator object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — end note]

**typename X::const_local_iterator**

*Result:* An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::const_iterator’s.

[Note 5: A const_local_iterator object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — end note]

**typename X::node_type**

*Result:* A specialization of a node-handle class template (24.2.5), such that the public nested types are the same types as the corresponding types in X.

X(n, hf, eq)

*Effects:* Constructs an empty container with at least n buckets, using hf as the hash function and eq as the key equality predicate.

*Complexity:* \( \Theta(n) \)

X(n, hf)

*Preconditions:* key_equal meets the Cpp17DefaultConstructible requirements.

*Effects:* Constructs an empty container with at least n buckets, using hf as the hash function and key_equal() as the key equality predicate.

*Complexity:* \( \Theta(n) \)

X(n)

*Preconditions:* hasher and key_equal meet the Cpp17DefaultConstructible requirements.

*Effects:* Constructs an empty container with at least n buckets, using hasher() as the hash function and key_equal() as the key equality predicate.

*Complexity:* \( \Theta(n) \)

X a = X();
X a;

*Preconditions:* hasher and key_equal meet the Cpp17DefaultConstructible requirements.

*Effects:* Constructs an empty container with an unspecified number of buckets, using hasher() as the hash function and key_equal() as the key equality predicate.

*Complexity:* Constant.

X(i, j, n, hf, eq)

*Preconditions:* value_type is Cpp17EmplaceConstructible into X from *i.

*Effects:* Constructs an empty container with at least n buckets, using hf as the hash function and eq as the key equality predicate, and inserts elements from [i, j) into it.

*Complexity:* Average case \( \Theta(N) \) (\( N \) is distance(i, j)), worst case \( \Theta(N^2) \).

X(i, j, n, hf)

*Preconditions:* key_equal meets the Cpp17DefaultConstructible requirements. value_type is Cpp17-EmplaceConstructible into X from *i.
Effects: Constructs an empty container with at least \(n\) buckets, using \(h_f\) as the hash function and \(\text{key_equal}()\) as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{distance}(i, j)\)), worst case \(\Theta(N^2)\).

\(X(i, j, n)\)

Preconditions: \(\text{hasher}\) and \(\text{key_equal}\) meet the Cpp17EmplaceConstructible requirements. \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast i\).

Effects: Constructs an empty container with at least \(n\) buckets, using \(\text{hasher}\) as the hash function and \(\text{key_equal}\) as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{distance}(i, j)\)), worst case \(\Theta(N^2)\).

\(X(i, j)\)

Preconditions: \(\text{hasher}\) and \(\text{key_equal}\) meet the Cpp17DefaultConstructible requirements. \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast i\).

Effects: Constructs an empty container with an unspecified number of buckets, using \(\text{hasher}\) as the hash function and \(\text{key_equal}\) as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{distance}(i, j)\)), worst case \(\Theta(N^2)\).

\(X(\text{from_range}, \text{rg}, n, h_f, \text{eq})\)

Preconditions: \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast \text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \(n\) buckets, using \(h_f\) as the hash function and \(\text{eq}\) as the key equality predicate, and inserts elements from \(\text{rg}\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{ranges::distance}(\text{rg})\)), worst case \(\Theta(N^2)\).

\(X(\text{from_range}, \text{rg}, n, h_f)\)

Preconditions: \text{key_equal} meets the Cpp17DefaultConstructible requirements. \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast \text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \(n\) buckets, using \(h_f\) as the hash function and \(\text{key_equal}\) as the key equality predicate, and inserts elements from \(\text{rg}\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{ranges::distance}(\text{rg})\)), worst case \(\Theta(N^2)\).

\(X(\text{from_range}, \text{rg}, n)\)

Preconditions: \text{hasher} and \text{key_equal} meet the Cpp17DefaultConstructible requirements. \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast \text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \(n\) buckets, using \(\text{hasher}\) as the hash function and \(\text{key_equal}\) as the key equality predicate, and inserts elements from \(\text{rg}\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{ranges::distance}(\text{rg})\)), worst case \(\Theta(N^2)\).

\(X(\text{from_range}, \text{rg})\)

Preconditions: \text{hasher} and \text{key_equal} meet the Cpp17DefaultConstructible requirements. \text{value_type} is Cpp17EmplaceConstructible into \(X\) from \(\ast \text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with an unspecified number of buckets, using \(\text{hasher}\) as the hash function and \(\text{key_equal}\) as the key equality predicate, and inserts elements from \(\text{rg}\) into it.

Complexity: Average case \(\Theta(N)\) (\(N\) is \(\text{ranges::distance}(\text{rg})\)), worst case \(\Theta(N^2)\).

\(X(i)\)

Effects: Equivalent to \(X(i.\text{begin}(), i.\text{end}())\).

\(X(i, n)\)

Effects: Equivalent to \(X(i.\text{begin}(), i.\text{end}(), n)\).

\(X(i, n, h_f)\)

Effects: Equivalent to \(X(i.\text{begin}(), i.\text{end}(), n, h_f)\).
X(il, n, hf, eq)

Effects: Equivalent to X(il.begin(), il.end(), n, hf, eq).

X(b)

Effects: In addition to the container requirements (24.2.2.2), copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in b.size(), worst case quadratic.

a = b

Result: X&

Effects: In addition to the container requirements, copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in b.size(), worst case quadratic.

a = il

Result: X&

Preconditions: value_type is Cpp17CopyInsertable into X and Cpp17CopyAssignable.

Effects: Assigns the range [il.begin(), il.end()) into a. All existing elements of a are either assigned to or destroyed.

Complexity: Average case linear in il.size(), worst case quadratic.

b.hash_function()

Result: hasher

Returns: b’s hash function.

Complexity: Constant.

b.key_eq()

Result: key_equal

Returns: b’s key equality predicate.

Complexity: Constant.

a_uniq.emplace(args)

Result: pair<iterator, bool>

Preconditions: value_type is Cpp17EmplaceConstructible into X from args.

Effects: Inserts a value_type object t constructed with std::forward<Args>(args)... if and only if there is no element in the container with key equivalent to the key of t.

Returns: The bool component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of t.

Complexity: Average case \(\Theta(1)\), worst case \(\Theta(a_uniq.size())\).

a_eq.emplace(args)

Result: iterator

Preconditions: value_type is Cpp17EmplaceConstructible into X from args.

Effects: Inserts a value_type object t constructed with std::forward<Args>(args)... .

Returns: An iterator pointing to the newly inserted element.

Complexity: Average case \(\Theta(1)\), worst case \(\Theta(a_eq.size())\).

a.emplace_hint(p, args)

Result: iterator

Preconditions: value_type is Cpp17EmplaceConstructible into X from args.

Effects: Equivalent to a.emplace(std::forward<Args>(args)...).
Returns: An iterator pointing to the element with the key equivalent to the newly inserted element. The `const_iterator p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.

```cpp
a_unique.insert(t)
```

Result: pair<iterator, bool>

Preconditions: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

Effects: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

Returns: The bool component of the returned pair indicates whether the insertion takes place, and the iterator component points to the element with key equivalent to the key of `t`.

Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.

```cpp
a_eq.insert(t)
```

Result: iterator

Preconditions: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

Effects: Inserts `t`.

Returns: An iterator pointing to the newly inserted element.

Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.

```cpp
a.insert(p, t)
```

Result: iterator

Preconditions: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

Effects: Equivalent to `a.insert(t)`. The iterator `p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Returns: An iterator pointing to the element with the key equivalent to that of `t`.

Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.

```cpp
a.insert(i, j)
```

Result: void

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

Effects: Equivalent to `a.insert(t)` for each element in `[i,j)`.

Complexity: Average case $\Theta(N)$, where `N` is `distance(i, j)`, worst case $\Theta(N(a.size() + 1))$.

```cpp
a.insert_range(rg)
```

Result: void

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into `X` from `ranges::begin(rg)`. `rg` and `a` do not overlap.

Effects: Equivalent to `a.insert(t)` for each element `t` in `rg`.

Complexity: Average case $\Theta(N)$, where `N` is `ranges::distance(rg)`, worst case $\Theta(N(a.size() + 1))$.

```cpp
a.insert(il)
```

Effects: Equivalent to `a.insert(il.begin(), il.end())`.

```cpp
a_unique.insert(nh)
```

Result: insert_return_type

Preconditions: `nh` is empty or `a_unique.get_allocator() == nh.get_allocator()` is true.
Effects: If \( nh \) is empty, has no effect. Otherwise, inserts the element owned by \( nh \) if and only if there is no element in the container with a key equivalent to \( nh.key() \).

Postconditions: If \( nh \) is empty, \( inserted = false \), \( position = \text{end()} \), and \( node \) is empty. Otherwise if the insertion took place, \( inserted = true \), \( position \) points to the inserted element, and \( node \) is empty; if the insertion failed, \( inserted = false \), \( node \) has the previous value of \( nh \), and \( position \) points to an element with a key equivalent to \( nh.key() \).

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{uniq}.size()) \).

\[ \text{a_eq.insert}(nh) \]

Result: iterator

Preconditions: \( nh \) is empty or \( \text{a_eq.get_allocator()} == \text{nh.get_allocator()} \) is true.

Effects: If \( nh \) is empty, has no effect and returns \( \text{a_eq.end()} \). Otherwise, inserts the element owned by \( nh \) and returns an iterator pointing to the newly inserted element.

Postconditions: \( nh \) is empty.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{eq}.size()) \).

\[ \text{a.insert}(q, nh) \]

Result: iterator

Preconditions: \( nh \) is empty or \( \text{a.get_allocator()} == \text{nh.get_allocator()} \) is true.

Effects: If \( nh \) is empty, has no effect and returns \( \text{a.end()} \). Otherwise, inserts the element owned by \( nh \) if and only if there is no element with key equivalent to \( nh.key() \) in containers with unique keys; always inserts the element owned by \( nh \) in containers with equivalent keys. The iterator \( q \) is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Postconditions: \( nh \) is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to \( nh.key() \).

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{size}) \).

\[ \text{a.extract}(k) \]

Result: node_type

Effects: Removes an element in the container with key equivalent to \( k \).

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{size}) \).

\[ \text{a_tran.extract}(kx) \]

Result: node_type

Effects: Removes an element in the container with key equivalent to \( kx \).

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{tran}.size()) \).

\[ \text{a.extract}(q) \]

Result: node_type

Effects: Removes the element pointed to by \( q \).

Returns: A node_type owning that element.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_{size}) \).

\[ \text{a.merge}(a2) \]

Result: void

Preconditions: \( \text{a.get_allocator()} == \text{a2.get_allocator()} \).

Effects: Attempts to extract each element in \( a2 \) and insert it into \( a \) using the hash function and key equality predicate of \( a \). In containers with unique keys, if there is an element in \( a \) with key equivalent to the key of an element from \( a2 \), then that element is not extracted from \( a2 \).
**Postconditions:** Pointers and references to the transferred elements of `a2` refer to those same elements but as members of `a`. Iterators referring to the transferred elements and all iterators referring to `a` will be invalidated, but iterators to elements remaining in `a2` will remain valid.

**Complexity:** Average case $\Theta(N)$, where $N$ is `a2.size()`, worst case $\Theta(N+a.size() + N)$.

**a.erase(k)**

- **Result:** `size_type`
- **Effects:** Erases all elements with key equivalent to `k`.
- **Returns:** The number of elements erased.
- **Complexity:** Average case $\Theta(a.count(k))$, worst case $\Theta(a.size())$.

**a_tran.erase(kx)**

- **Result:** `size_type`
- **Effects:** Erases all elements with key equivalent to `kx`.
- **Returns:** The number of elements erased.
- **Complexity:** Average case $\Theta(a_tran.count(kx))$, worst case $\Theta(a_tran.size())$.

**a.erase(q)**

- **Result:** `iterator`
- **Effects:** Erases the element pointed to by `q`.
- **Returns:** The iterator immediately following `q` prior to the erasure.
- **Complexity:** Average case $\Theta(1)$, worst case $\Theta(a.size())$.

**a.erase(r)**

- **Result:** `iterator`
- **Effects:** Erases the element pointed to by `r`.
- **Returns:** The iterator immediately following `r` prior to the erasure.
- **Complexity:** Average case $\Theta(1)$, worst case $\Theta(a.size())$.

**a.erase(q1, q2)**

- **Result:** `iterator`
- **Effects:** Erases all elements in the range `[q1, q2)`.
- **Returns:** The iterator immediately following the erased elements prior to the erasure.
- **Complexity:** Average case linear in `distance(q1, q2)`, worst case $\Theta(a.size())$.

**a.clear()**

- **Result:** `void`
- **Effects:** Erases all elements in the container.
- **Postconditions:** `a.empty()` is `true`.
- **Complexity:** Linear in `a.size()`.

**b.find(k)**

- **Result:** `iterator; const_iterator` for constant `b`.
- **Returns:** An iterator pointing to an element with key equivalent to `k`, or `b.end()` if no such element exists.
- **Complexity:** Average case $\Theta(1)$, worst case $\Theta(b.size())$.

**a_tran.find(ke)**

- **Result:** `iterator; const_iterator` for constant `a_tran`.
- **Returns:** An iterator pointing to an element with key equivalent to `ke`, or `a_tran.end()` if no such element exists.

§ 24.2.8.1
Complexity: Average case $O(1)$, worst case $O(a_{\text{tran}.\text{size}}())$.

\[\text{b.count}(k)\]

\textit{Result: size_type}

\textit{Returns:} The number of elements with key equivalent to $k$.

\textit{Complexity:} Average case $O(\text{b.count}(k))$, worst case $O(\text{b.size}())$.

\[\text{a_{\text{tran}.\text{count}}}(ke)\]

\textit{Result: size_type}

\textit{Returns:} The number of elements with key equivalent to $ke$.

\textit{Complexity:} Average case $O(\text{a_{\text{tran}.\text{count}}}(ke))$, worst case $O(\text{a_{\text{tran}.\text{size}}()}$).

\[\text{b.contains}(k)\]

\textit{Effects:} Equivalent to \text{b.find}(k) \neq \text{b.end}().

\[\text{a_{\text{tran}.\text{contains}}}(ke)\]

\textit{Effects:} Equivalent to \text{a_{\text{tran}.\text{find}}}(ke) \neq \text{a_{\text{tran}.\text{end}}()}.

\[\text{b.equal_range}(k)\]

\textit{Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant \text{b}.}

\textit{Returns:} A range containing all elements with keys equivalent to $k$. Returns \text{make_pair}(\text{b.end}(), \text{b.end}()) if no such elements exist.

\textit{Complexity:} Average case $O(\text{b.count}(k))$, worst case $O(\text{b.size}())$.

\[\text{a_{\text{tran}.\text{equal_range}}}(ke)\]

\textit{Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant \text{a_{\text{tran}}.}

\textit{Returns:} A range containing all elements with keys equivalent to $ke$. Returns \text{make_pair}(\text{a_{\text{tran}.end}()}, \text{a_{\text{tran}.end}()}) if no such elements exist.

\textit{Complexity:} Average case $O(\text{a_{\text{tran}.\text{count}}}(ke))$, worst case $O(\text{a_{\text{tran}.\text{size}}()}$).

\[\text{b.bucket_count}()\]

\textit{Returns:} The number of buckets that \text{b} contains.

\textit{Complexity:} Constant.

\[\text{b.max_bucket_count}()\]

\textit{Result: size_type}

\textit{Returns:} An upper bound on the number of buckets that \text{b} can ever contain.

\textit{Complexity:} Constant.

\[\text{b.bucket}(k)\]

\textit{Result: size_type}

\textit{Preconditions:} $\text{b.bucket_count}() > 0$.

\textit{Returns:} The index of the bucket in which elements with keys equivalent to $k$ would be found, if any such element existed. The return value is in the range $[0, \text{b.bucket_count}())$.

\textit{Complexity:} Constant.

\[\text{a_{\text{tran}.\text{bucket}}}(ke)\]

\textit{Result: size_type}

\textit{Preconditions:} $\text{a_{\text{tran}.\text{bucket_count}}()} > 0$.

\textit{Postconditions:} The return value is in the range $[0, \text{a_{\text{tran}.\text{bucket_count}}()}$).
Returns: The index of the bucket in which elements with keys equivalent to \texttt{ke} would be found, if any such element existed.

Complexity: Constant.

\( b\text{.bucket}\_size(n) \)

Result: \texttt{size\_type}

Preconditions: \texttt{n} shall be in the range \([0, b\text{.bucket}\_count())\).

Returns: The number of elements in the \(n\)th bucket.

Complexity: \(O(b\text{.bucket}\_size(n))\)

\( b\text{.begin}(n) \)

Result: \texttt{local\_iterator; const\_local\_iterator} for constant \texttt{b}.

Preconditions: \texttt{n} is in the range \([0, b\text{.bucket}\_count())\).

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then \(b\text{.begin}(n) == b\text{.end}(n)\).

Complexity: Constant.

\( b\text{.end}(n) \)

Result: \texttt{local\_iterator; const\_local\_iterator} for constant \texttt{b}.

Preconditions: \texttt{n} is in the range \([0, b\text{.bucket}\_count())\).

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

\( b\text{.cbegin}(n) \)

Result: \texttt{const\_local\_iterator}

Preconditions: \texttt{n} shall be in the range \([0, b\text{.bucket}\_count())\).

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then \(b\text{.cbegin}(n) == b\text{.cend}(n)\).

Complexity: Constant.

\( b\text{.cend}(n) \)

Result: \texttt{const\_local\_iterator}

Preconditions: \texttt{n} is in the range \([0, b\text{.bucket}\_count())\).

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.

\( b\text{.load}\_factor() \)

Result: \texttt{float}

Returns: The average number of elements per bucket.

Complexity: Constant.

\( b\text{.max}\_load\_factor() \)

Result: \texttt{float}

Returns: A positive number that the container attempts to keep the load factor less than or equal to. The container automatically increases the number of buckets as necessary to keep the load factor below this number.

Complexity: Constant.

\( a\text{.max}\_load\_factor(z) \)

Result: \texttt{void}

Preconditions: \texttt{z} is positive. May change the container's maximum load factor, using \texttt{z} as a hint.
Complexity: Constant.

\[ \text{a.rehash}(n) \]

Result: \text{void}

Postconditions: \text{a.bucket_count()} \geq \text{a.size()} / \text{a.max_load_factor()} and \text{a.bucket_count()} \geq n.

Complexity: Average case linear in \text{a.size()}, worst case quadratic.

\[ \text{a.reserve}(n) \]

Effects: Equivalent to \text{a.rehash(ceil}(n / \text{a.max_load_factor}()))

Two unordered containers \text{a} and \text{b} compare equal if \text{a.size()} == \text{b.size()} and, for every equivalent-key group \([\text{Ea}_1, \text{Ea}_2]\) obtained from \text{a.equal_range}(\text{Ea}_1), there exists an equivalent-key group \([\text{Eb}_1, \text{Eb}_2]\) obtained from \text{b.equal_range}(\text{Ea}_1), such that \text{is_permutation}(\text{Ea}_1, \text{Ea}_2, \text{Eb}_1, \text{Eb}_2) returns \text{true}. For \text{unordered_set} and \text{unordered_map}, the complexity of \text{operator==} (i.e., the number of calls to the == operator of the \text{value_type}, to the predicate returned by \text{key_eq()}, and to the hasher returned by \text{hash_type}()) is proportional to \(N\) in the average case and to \(N^2\) in the worst case, where \(N = \text{a.size}()\). For \text{unordered_multiset} and \text{unordered_multimap}, the complexity of \text{operator==} is proportional to \(\sum E_i^2\) in the average case and to \(N^2\) in the worst case, where \(N = \text{a.size}()\), and \(E_i\) is the size of the \(i\)th equivalent-key group in \text{a}. However, if the respective elements of each corresponding pair of equivalent-key groups \(\text{Ea}_i\) and \(\text{Eb}_i\) are arranged in the same order (as is commonly the case, e.g., if \text{a} and \text{b} are unmodified copies of the same container), then the average-case complexity for \text{unordered_multiset} and \text{unordered_multimap} becomes proportional to \(N\) (but worst-case complexity remains \(O(N^2)\), e.g., for a pathologically bad hash function). The behavior of a program that uses \text{operator==} or \text{operator!=} on unordered containers is undefined unless the \text{Pred} function object has the same behavior for both containers and the equality comparison function for \text{Key} is a refinement\(^{207}\) of the partition into equivalent-key groups produced by \text{Pred}.

The iterator types \text{iterator} and \text{const_iterator} of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the \text{key} type and \text{value} type are the same, both \text{iterator} and \text{const_iterator} are constant iterators.

The \text{insert}, \text{insert_range}, and \text{emplace} members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The \text{erase} members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

The \text{insert}, \text{insert_range}, and \text{emplace} members shall not affect the validity of iterators if \((N+n) \leq z * B\), where \(N\) is the number of elements in the container prior to the insert operation, \(n\) is the number of elements inserted, \(B\) is the container’s bucket count, and \(z\) is the container’s maximum load factor.

The \text{extract} members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a \text{node_type} is undefined behavior. References and pointers to an element obtained while it is owned by a \text{node_type} are invalidated if the element is successfully inserted.

The member function templates \text{find}, \text{count}, \text{equal_range}, \text{contains}, \text{extract}, \text{erase}, and \text{bucket} shall not participate in overload resolution unless the \text{qualified-ids} \text{Pred::is_transparent} and \text{Hash::is_transparent} are both valid and denote types (13.10.3). Additionally, the member function templates \text{extract} and \text{erase} shall not participate in overload resolution if \text{is_convertible_v<K&&, iterator>} || \text{is_convertible_v<K&&, const_iterator>} is \text{true}, where \(K\) is the type substituted as the first template argument.

A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

\((248.1)\) It has an \text{InputIterator} template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

\((248.2)\) It has an \text{Allocator} template parameter and a type that does not qualify as an allocator is deduced for that parameter.

\((248.3)\) It has a \text{Hash} template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.

\(^{207}\) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
It has a `Pred` template parameter and a type that qualifies as an allocator is deduced for that parameter.

24.2.8.2 Exception safety guarantees

1. For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s `Hash` or `Pred` object (if any).

2. For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

3. For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s `Hash` or `Pred` object (if any).

4. For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container’s hash function or comparison function, the `rehash()` function has no effect.

24.3 Sequence containers

24.3.1 In general

1. The headers `<array>` (24.3.2), `<deque>` (24.3.3), `<forward_list>` (24.3.4), `<list>` (24.3.5), and `<vector>` (24.3.6) define class templates that meet the requirements for sequence containers.

2. The following exposition-only alias template may appear in deduction guides for sequence containers:

   ```cpp
   template<class InputIterator>
   using iter_value_type = typename iterator_traits<InputIterator>::value_type;  // exposition only
   ```

24.3.2 Header `<array>` synopsis

// mostly freestanding
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2

namespace std {
    // 24.3.7, class template array
    template<class T, size_t N> struct array;  // partially freestanding

    template<class T, size_t N>
    constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);

    template<class T, size_t N>
    constexpr synth_three_way_result<T>
        operator<=>(const array<T, N>& x, const array<T, N>& y);

    // 24.3.7.4, specialized algorithms
    template<class T, size_t N>
    constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)))

    // 24.3.7.6, array creation functions
    template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
    template<class T, size_t N>
    constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);

    // 24.3.7.7, tuple interface
    template<class T> struct tuple_size;
    template<size_t I, class T> struct tuple_element;
    template<size_t I, class T, size_t N>
    struct tuple_size<array<T, N>>;
    template<size_t I, class T, size_t N>
    struct tuple_element<I, array<T, N>>;

    template<size_t I, class T, size_t N> constexpr T& get(array<T, N>&) noexcept;
    template<size_t I, class T, size_t N> constexpr T&& get(array<T, N>&&) noexcept;
    template<size_t I, class T, size_t N> constexpr const T& get(const array<T, N>&) noexcept;

§ 24.3.2
template<
    size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&&) noexcept;
}

24.3.7 Class template array

24.3.7.1 Overview

The header <array> defines a class template for storing fixed-size sequences of objects. An array is a contiguous container (24.2.2.2). An instance of array<T, N> stores N elements of type T, so that size() == N is an invariant.

An array is an aggregate (9.4.2) that can be list-initialized with up to N elements whose types are convertible to T.

An array meets all of the requirements of a container (24.2.2.2) and of a reversible container (24.2.2.3), except that a default constructed array object is not empty if N > 0. An array meets some of the requirements of a sequence container (24.2.4). Descriptions are provided here only for operations on array that are not described in one of these tables and for operations where there is additional semantic information.

array<T, N> is a structural type (13.2) if T is a structural type. Two values a1 and a2 of type array<T, N> are template-argument-equivalent (13.6) if and only if each pair of corresponding elements in a1 and a2 are template-argument-equivalent.

The types iterator and const_iterator meet the constexpr iterator requirements (25.3.1).

namespace std {
    template<class T, size_t N>
    struct array {
        // types
        using value_type = T;
        using pointer = T*;
        using const_pointer = const T*;
        using reference = T&;
        using const_reference = const T&;
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using iterator = implementation-defined;  // see 24.2
        using const_iterator = implementation-defined;  // see 24.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // no explicit construct/copy/destroy for aggregate type
        constexpr void fill(const T& u);
        constexpr void swap(array&) noexcept(is_nothrow_swappable_v<T>);

        // iterators
        constexpr iterator begin() noexcept;
    }

    § 24.3.7.1 933
constexpr const_iterator begin() const noexcept;
constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_iterator cbegin() const noexcept;
constexpr const_iterator cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;

// element access
constexpr reference operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr reference at(size_type n);
constexpr const_reference at(size_type n) const;
constexpr reference front();
constexpr const_reference front() const;
constexpr reference back();
constexpr const_reference back() const;
constexpr T * data() noexcept;
constexpr const T * data() const noexcept;

template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;

24.3.7.2 Constructors, copy, and assignment

1 The conditions for an aggregate (9.4.2) shall be met. Class array relies on the implicitly-declared special
member functions (11.4.5.2, 11.4.7, 11.4.5.3) to conform to the container requirements table in 24.2. In
addition to the requirements specified in the container requirements table, the implicit move constructor and
move assignment operator for array require that T be Cpp17MoveConstructible or Cpp17MoveAssignable,
respectively.

template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;

2 Mandates: (is_same_v<T, U> && ...) is true.

24.3.7.3 Member functions

constexpr size_type size() const noexcept;

Returns: N.

constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty array,
data() == addressof(front()) is true.

constexpr void fill(const T& u);

Effects: As if by fill_n(begin(), N, u).
constexpr void swap(array& y) noexcept(is_nothrow_swappable_v<T>);

Effects: Equivalent to swap_ranges(begin(), end(), y.begin()).

[Note 1: Unlike the swap function for other containers, array::swap takes linear time, can exit via an exception, and does not cause iterators to become associated with the other container. —end note]

24.3.7.4 Specialized algorithms

template<class T, size_t N>
constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

Constraints: N == 0 or is_swappable_v<T> is true.

Effects: As if by x.swap(y).

Complexity: Linear in N.

24.3.7.5 Zero-sized arrays

array shall provide support for the special case N == 0.

In the case that N == 0, begin() == end() == unique value. The return value of data() is unspecified.

The effect of calling front() or back() for a zero-sized array is undefined.

Member function swap() shall have a non-throwing exception specification.

24.3.7.6 Array creation functions

template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);

Mandates: is_array_v<T> is false and is_constructible_v<T, T&> is true.

Preconditions: T meets the Cpp17CopyConstructible requirements.

Returns: {{ a[0], ..., a[N - 1] }}.

template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);

Mandates: is_array_v<T> is false and is_move_constructible_v<T> is true.

Preconditions: T meets the Cpp17MoveConstructible requirements.

Returns: {{ std::move(a[0]), ..., std::move(a[N - 1]) }}.

24.3.7.7 Tuple interface

template<class T, size_t I, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };
24.3.8 Class template deque

24.3.8.1 Overview

A deque is a sequence container that supports random access iterators (25.3.5.7). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

A deque meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container, including the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template<class T, class Allocator = allocator<T>>
    class deque {
        public:
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 24.2
            using difference_type = implementation-defined; // see 24.2
            using iterator = implementation-defined; // see 24.2
            using const_iterator = implementation-defined; // see 24.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;

            // 24.3.8.2, construct/copy/destroy
            deque() : deque(Allocator()) {} // default constructor
            explicit deque(const Allocator&);
            deque(size_type n, const Allocator& = Allocator());
            deque(size_type n, const T& value, const Allocator& = Allocator());
            template<class InputIterator>
            deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
            template<container-compatible-range<T> R>
            deque(from_range_t, R&& rg, const Allocator& = Allocator());
            deque(const deque& x);
            deque(deque&&);
            deque(const deque&, const type_identity_t<Allocator>&);
            deque(deque&&, const type_identity_t<Allocator>&);
            deque(initializer_list<T>, const Allocator& = Allocator());
            ~deque();
            deque& operator=(const deque& x);
            deque& operator=(deque&& x) noexcept(allocator_traits<Allocator>::is_always_equal::value);
            deque& operator=(initializer_list<T>);

            template<class InputIterator>
            void assign(InputIterator first, InputIterator last);
            template<container-compatible-range<T> R>
            void assign_range(R&& rg);
            void assign(size_type n, const T& t);
            void assign(initializer_list<T>);

            allocator_type get_allocator() const noexcept;

            // iterators
            iterator begin() noexcept;
            const_iterator begin() const noexcept;
            iterator end() noexcept;
            const_iterator end() const noexcept;
            reverse_iterator rbegin() noexcept;
        }
    }
}
```

void clear() noexcept;

};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
deque<InputIterator, Allocator = Allocator>()
-> deque<iter-value-type<InputIterator>, Allocator>;

§ 24.3.8.1 937
template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
    deque(from_range_t, R&&, Allocator = Allocator())
    -> deque<ranges::range_value_t<R>, Allocator>;

24.3.8.2 Constructors, copy, and assignment

explicit deque(const Allocator&);
1
   Effects: Constructs an empty deque, using the specified allocator.
2
   Complexity: Constant.

explicit deque(size_type n, const Allocator& = Allocator());
3
   Preconditions: T is Cpp17DefaultInsertable into *this.
4
   Effects: Constructs a deque with n default-inserted elements using the specified allocator.
5
   Complexity: Linear in n.

deque(size_type n, const T& value, const Allocator& = Allocator());
6
   Preconditions: T is Cpp17CopyInsertable into *this.
7
   Effects: Constructs a deque with n copies of value, using the specified allocator.
8
   Complexity: Linear in n.

template<class InputIterator>
    deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
9
   Effects: Constructs a deque equal to the range [first, last), using the specified allocator.
10
   Complexity: Linear in distance(first, last).

template<container-compatible-range<T> R>
    deque(from_range_t, R&& rg, const Allocator& = Allocator());
11
   Effects: Constructs a deque with the elements of the range rg, using the specified allocator.
12
   Complexity: Linear in ranges::distance(rg).

24.3.8.3 Capacity

void resize(size_type sz);
1
   Preconditions: T is Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.
2
   Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends
   sz - size() default-inserted elements to the sequence.

void resize(size_type sz, const T& c);
3
   Preconditions: T is Cpp17CopyInsertable into *this.
4
   Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends
   sz - size() copies of c to the sequence.

void shrink_to_fit();
5
   Preconditions: T is Cpp17MoveInsertable into *this.
6
   Effects: shrink_to_fit is a non-binding request to reduce memory use but does not change the size of
   the sequence.

   [Note 1: The request is non-binding to allow latitude for implementation-specific optimizations. — end note]

   If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor
   of a non-Cpp17CopyInsertable T, then there are no effects.

   Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise
   constant.

   Remarks: If the size is not equal to the old capacity, then invalidates all the references, pointers, and
   iterators referring to the elements in the sequence, as well as the past-the-end iterator.
24.3.8.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position,
                    InputIterator first, InputIterator last);
    template<container-compatible-range R>
        iterator insert_range(const_iterator position, R&& rg);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);

Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of T.

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();

Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.

[Note 1: pop_front and pop_back are erase operations. — end note]

Throws: Nothing unless an exception is thrown by the assignment operator of T.

Complexity: The number of calls to the destructor of T is the same as the number of elements erased, but the number of calls to the assignment operator of T is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

24.3.8.5 Erasure

template<class T, class Allocator, class U>
    typename deque<T, Allocator>::size_type
        erase(deque<T, Allocator>& c, const U& value);

Effects: Equivalent to:

```cpp
class T { public:
    // Assume there is an appropriate destruct() member function
    void destruct(const U& value);  // For example:
    void destruct(T&& x) { destruct(x.value()); }  // for std::unique_ptr
private:
    // Some implementation that uses the copy constructor
    T(T&& x) { destruct(x); }
};
```

auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
template<class T, class Allocator, class Predicate>
    typename deque<T, Allocator>::size_type
    erase_if(deque<T, Allocator>& c, Predicate pred);

    Effects: Equivalent to:
            auto it = remove_if(c.begin(), c.end(), pred);
            auto r = distance(it, c.end());
            c.erase(it, c.end());
            return r;

24.3.9 Class template forward_list

24.3.9.1 Overview

A forward_list is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported.

[Note 1: It is intended that forward_list have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — end note]

2 A forward_list meets all of the requirements of a container (24.2.2.2), except that the size() member function is not provided and operator== has linear complexity. A forward_list also meets all of the requirements for an allocator-aware container (24.2.2.5). In addition, a forward_list provides the assign member functions and several of the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on forward_list that are not described in that table or for operations where there is additional semantic information.

[Note 2: Modifying any list requires access to the element preceding the first element of interest, but in a forward_list there is no constant-time way to access a preceding element. For this reason, erase_after and splice_after take fully-open ranges, not semi-open ranges. — end note]
template<class InputIterator>
    void assign(InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    void assign_range(R&& rg);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// 24.3.9.3, iterators
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cbefore_begin() const noexcept;
const_iterator cend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type max_size() const noexcept;

// 24.3.9.4, element access
reference front();
const_reference front() const;

// 24.3.9.5, modifiers
template<class... Args> reference emplace_front(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
    void prepend_range(R&& rg);
void pop_front();
template<class... Args> iterator emplace_after(const_iterator position, Args&&... args);
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);
iterator insert_after(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
iterator insert_after(const_iterator position, initializer_list<T> il);
template<container-compatible-range<T> R>
    iterator insert_range_after(const_iterator position, R&& rg);
iterator erase_after(const_iterator position);
iterator erase_after(const_iterator position, const_iterator last);
void swap(forward_list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void resize(size_type sz);
void resize(size_type sz, const value_type& c);
void clear() noexcept;

// 24.3.9.6, forward_list operations
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
void splice_after(const_iterator position, forward_list& x,
    const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);

void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);

void sort();
template<class Compare> void sort(Compare comp);

void reverse() noexcept;

An incomplete type T may be used when instantiating forward_list if the allocator meets the allocator completeness requirements (16.4.4.6.2). T shall be complete before any member of the resulting specialization of forward_list is referenced.

24.3.9.2 Constructors, copy, and assignment

explicit forward_list(const Allocator&);

Effects: Constructs an empty forward_list object using the specified allocator.
Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());

Preconditions: T is Cpp17DefaultInsertable into *this.
Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.
Complexity: Linear in n.

forward_list(size_type n, const T& value, const Allocator& = Allocator());

Preconditions: T is Cpp17CopyInsertable into *this.
Effects: Constructs a forward_list object with n copies of value using the specified allocator.
Complexity: Linear in n.

template<class InputIterator>
forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());

Effects: Constructs a forward_list object equal to the range [first, last).
Complexity: Linear in distance(first, last).

template<container-compatible-range<T> R>
forward_list(from_range_t, R&& rg, const Allocator& = Allocator());

Effects: Constructs a forward_list object with the elements of the range rg.
Complexity: Linear in ranges::distance(rg).
24.3.9.3 Iterators

iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;

1 Effects: cbefore_begin() is equivalent to const_cast<forward_list const&>(*this).before_begin().
2 Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by begin().
3 Remarks: before_begin() == end() shall equal false.

24.3.9.4 Element access

reference front();
const_reference front() const;

1 Returns: *begin()

24.3.9.5 Modifiers

None of the overloads of insert_after shall affect the validity of iterators and references, and erase_after shall invalidate only iterators and references to the erased elements. If an exception is thrown during insert_after there shall be no effect. Inserting \( n \) elements into a forward_list is linear in \( n \), and the number of calls to the copy or move constructor of \( T \) is exactly equal to \( n \). Erasing \( n \) elements from a forward_list is linear in \( n \) and the number of calls to the destructor of type \( T \) is exactly equal to \( n \).

template<class... Args> reference emplace_front(Args&&... args);

1 Effects: Inserts an object of type value_type constructed with value_type(std::forward<Args>(args)...). at the beginning of the list.

void push_front(const T& x);
void push_front(T&& x);

2 Effects: Inserts a copy of \( x \) at the beginning of the list.

template<container-compatible-range< T>> R
void prepend_range(R&& rg);

4 Effects: Inserts a copy of each element of \( rg \) at the beginning of the list.

[Note 1: The order of elements is not reversed. — end note]

void pop_front();

5 Effects: As if by erase_after(before_begin()).

iterator insert_after(const_iterator position, const T& x);

6 Preconditions: \( T \) is Cpp17CopyInsertable into forward_list. position is before_begin() or is a dereferenceable iterator in the range [begin(),end()).
7 Effects: Inserts a copy of \( x \) after position.
8 Returns: An iterator pointing to the copy of \( x \).

iterator insert_after(const_iterator position, T&& x);

9 Preconditions: \( T \) is Cpp17MoveInsertable into forward_list. position is before_begin() or is a dereferenceable iterator in the range [begin(),end()).
10 Effects: Inserts a copy of \( x \) after position.
11 Returns: An iterator pointing to the copy of \( x \).

iterator insert_after(const_iterator position, size_type n, const T& x);

12 Preconditions: \( T \) is Cpp17CopyInsertable into forward_list. position is before_begin() or is a dereferenceable iterator in the range [begin(),end()).
13 Effects: Inserts \( n \) copies of \( x \) after position.
Returns: An iterator pointing to the last inserted copy of x, or position if n == 0 is true.

```cpp
template<class InputIterator>
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
```

Preconditions: T is Cpp17EmplaceConstructible into forward_list from *first. position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). Neither first nor last are iterators in *this.

Effects: Inserts copies of elements in [first, last) after position.

Returns: An iterator pointing to the last inserted element, or position if first == last is true.

```cpp
template<container-compatible-range<T> R>
iterator insert_range_after(const_iterator position, R&& rg);
```

Preconditions: T is Cpp17EmplaceConstructible into forward_list from *ranges::begin(rg). position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). rg and *this do not overlap.

Effects: Inserts copies of elements in the range rg after position.

Returns: An iterator pointing to the last inserted element, or position if rg is empty.

```cpp
iterator insert_after(const_iterator position, initializer_list<T> il);
```

Effects: Equivalent to: return insert_after(position, il.begin(), il.end());

```cpp
template<class... Args>
iterator emplace_after(const_iterator position, Args&&... args);
```

Preconditions: T is Cpp17EmplaceConstructible into forward_list from std::forward<Args>(args).... position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).

Effects: Inserts an object of type value_type direct-non-list-initialized with std::forward<Args>(args).... after position.

Returns: An iterator pointing to the new object.

```cpp
iterator erase_after(const_iterator position);
```

Preconditions: The iterator following position is dereferenceable.

Effects: Erases the element pointed to by the iterator following position.

Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.

Throws: Nothing.

```cpp
iterator erase_after(const_iterator position, const_iterator last);
```

Preconditions: All iterators in the range (position, last) are dereferenceable.

Effects: Erases the elements in the range (position, last).

Returns: last.

Throws: Nothing.

```cpp
void resize(size_type sz);
```

Preconditions: T is Cpp17DefaultInsertable into *this.

Effects: If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) default-inserted elements at the end of the list.

```cpp
void resize(size_type sz, const value_type& c);
```

Preconditions: T is Cpp17CopyInsertable into *this.

Effects: If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) copies of c at the end of the list.
void clear() noexcept;

Effects: Erases all elements in the range \([\text{begin()}, \text{end()}]\).

Remarks: Does not invalidate past-the-end iterators.

### 24.3.9.6 Operations

In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 27.2. The semantics of \(i + n\), where \(i\) is an iterator into the list and \(n\) is an integer, are the same as those of `next(i, n)`. The expression \(i - n\), where \(i\) is an iterator into the list and \(n\) is an integer, means an iterator \(j\) such that \(j + n == i\) is true. For `merge` and `sort`, the definitions and requirements in 27.8 apply.

```cpp
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[\text{begin()}, \text{end()}]`. `get_allocator()` == `x.get_allocator()` is true. `addressof(x) != this` is true.

Effects: Inserts the contents of \(x\) after `position`, and \(x\) becomes empty. Pointers and references to the moved elements of \(x\) now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into \(x\).

Throws: Nothing.

Complexity: \(\theta(\text{distance(x.begin()), x.end()})\)

```cpp
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[\text{begin()}, \text{end()}]`. The iterator following \(i\) is a dereferenceable iterator in \(x\). `get_allocator()` == `x.get_allocator()` is true.

Effects: Inserts the element following \(i\) into `*this`, following `position`, and removes it from \(x\). The result is unchanged if `position == i` or `position == +i`. Pointers and references to `++i` continue to refer to the same element but as a member of `*this`. Iterators to `++i` continue to refer to the same element, but now behave as iterators into `*this`, not into \(x\).

Throws: Nothing.

Complexity: \(\theta(1)\)

```cpp
void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);
```

Preconditions: `position` is `before_begin()` or is a dereferenceable iterator in the range `[\text{begin()}, \text{end()}]`. `(first, last)` is a valid range in \(x\), and all iterators in the range `(first, last)` are dereferenceable. `position` is not an iterator in the range `(first, last)`. `get_allocator()` == `x.get_allocator()` is true.

Effects: Inserts elements in the range `(first, last)` after `position` and removes the elements from \(x\). Pointers and references to the moved elements of \(x\) now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into \(x\).

Complexity: \(\theta(\text{distance(first, last)})\)

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

Effects: Erases all the elements in the list referred to by a list iterator \(i\) for which the following conditions hold: \(*i == value\) (for `remove()`), `pred(*i)` is true (for `remove_if()`). Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

§ 24.3.9.6
Complexity: Exactly `distance(begin(), end())` applications of the corresponding predicate.
Remarks: Stable (16.4.6.8).

```cpp
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
```

Let `binary_pred` be `equal_to<>{}` for the first overload.

Preconditions: `binary_pred` is an equivalence relation.

Effects: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator `i` in the range `[begin() + 1, end())` for which `binary_pred(*i, *(i - 1))` is `true`. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.
Throws: Nothing unless an exception is thrown by the predicate.

Complexity: If `empty()` is `false`, exactly `distance(begin(), end()) - 1` applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);
```

Let `comp` be `less<>` for the first two overloads.

Preconditions: `*this` and `x` are both sorted with respect to the comparator `comp`, and `get_allocator()` == `x.get_allocator()` is `true`.

Effects: If `addressof(x) == this`, there are no effects. Otherwise, merges the two sorted ranges `[begin(), end())` and `[x.begin(), x.end())`. The result is a range that is sorted with respect to the comparator `comp`. Pointers and references to the moved elements of `x` now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into `x`.

Complexity: At most `distance(begin(), end()) + distance(x.begin(), x.end()) - 1` comparisons if `addressof(x) != this`; otherwise, no comparisons are performed.

Remarks: Stable (16.4.6.8). If `addressof(x) != this`, `x` is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison, there are no effects.

```cpp
void sort();
template<class Compare> void sort(Compare comp);
```

Effects: Sorts the list according to the `operator<` or the `comp` function object. If an exception is thrown, the order of the elements in `*this` is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately `N log N` comparisons, where `N` is `distance(begin(), end())`.
Remarks: Stable (16.4.6.8).

```cpp
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

### 24.3.9.7 Erasure

```cpp
template<class T, class Allocator, class U>
typename forward_list<T, Allocator>::size_type erase(forward_list<T, Allocator>& c, const U& value);
```

Effects: Equivalent to: `return erase_if(c, [&](auto& elem) { return elem == value; });`
template<class T, class Allocator, class Predicate>
typename forward_list<T, Allocator>::size_type
erase_if(forward_list<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: return c.remove_if(pred);

24.3.10 Class template list

24.3.10.1 Overview

A list is a sequence container that supports bidirectional iterators and allows constant time insert and
erase operations anywhere within the sequence, with storage management handled automatically. Unlike
vectors (24.3.11) and deques (24.3.8), fast random access to list elements is not supported, but many
algorithms only need sequential access anyway.

A list meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an
allocator-aware container (24.2.2.5), and of a sequence container, including most of the optional sequence
container requirements (24.2.4). The exceptions are the operator[[] and at member functions, which are
not provided.208 Descriptions are provided here only for operations on list that are not described in one of
these tables or for operations where there is additional semantic information.

namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
    public:
        // types
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation_defined; // see 24.2
        using difference_type = implementation_defined; // see 24.2
        using iterator = implementation_defined; // see 24.2
        using const_iterator = implementation_defined; // see 24.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 24.3.10.2, construct/copy/destroy
        list() : list(Allocator()) {}  
        explicit list(const Allocator&);  
        explicit list(size_type n, const Allocator& = Allocator());  
        list(size_type n, const T& value, const Allocator& = Allocator());  
        template<class InputIterator>
        list(InputIterator first, InputIterator last, const Allocator& = Allocator());  
        template<container-compatible-range<T> R>
        list(from_range_t, R&& rg, const Allocator& = Allocator());  
        list(const list& x);  
        list(const list&, const type_identity_t<Allocator>&);  
        list(list&& x);  
        list(const list&, const type_identity_t<Allocator>&);  
        list(initializer_list<T>, const Allocator& = Allocator());  
        ~list();  
        list& operator=(const list& x);  
        list& operator=(list&& x)  
        noexcept(allocator_traits<Allocator>::is_always_equal::value);  
        list& operator=(initializer_list<T>);  
        template<class InputIterator>
        void assign(InputIterator first, InputIterator last);  
        template<container-compatible-range<T> R>
        void assign_range(R&& rg);  
        void assign(size_type n, const T& t);  
        void assign(initializer_list<T>);  
        allocator_type get_allocator() const noexcept;
    }

    208) These member functions are only provided by containers whose iterators are random access iterators.

§ 24.3.10.1

const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 24.3.10.3, capacity
bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);

// element access
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 24.3.10.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
void prepend_range(R&& rg);
void pop_front();
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
void append_range(R&& rg);
void pop_back();

template<class... Args>
iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T> il);
iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);
void swap(list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

// 24.3.10.5, list operations
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
void splice(const_iterator position, list x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate>
size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);
template<class Compare>
void merge(list& x, Compare comp);
template<class Compare>
void merge(list&& x, Compare comp);

void sort();
template<class Compare>
void sort(Compare comp);

void reverse() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>>
list(InputIterator, InputIterator, Allocator = Allocator())
  -> list<iter-value-type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
list(from_range_t, R&&, Allocator = Allocator())
  -> list<ranges::range_value_t<R>, Allocator>;
```

3 An incomplete type T may be used when instantiating list if the allocator meets the allocator completeness requirements (16.4.4.6.2). T shall be complete before any member of the resulting specialization of list is referenced.

### 24.3.10.2 Constructors, copy, and assignment

```cpp
explicit list(const Allocator&);
```

1 Effects: Constructs an empty list, using the specified allocator.

2 Complexity: Constant.

```cpp
explicit list(size_type n, const Allocator& = Allocator());
```

3 Preconditions: T is Cpp17DefaultInsertable into *this.

4 Effects: Constructs a list with n default-inserted elements using the specified allocator.

5 Complexity: Linear in n.

```cpp
list(size_type n, const T& value, const Allocator& = Allocator());
```

6 Preconditions: T is Cpp17CopyInsertable into *this.

7 Effects: Constructs a list with n copies of value, using the specified allocator.

8 Complexity: Linear in n.

```cpp
template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

9 Effects: Constructs a list equal to the range [first, last).

10 Complexity: Linear in distance(first, last).

```cpp
template<container-compatible-range<T> R>
list(from_range_t, R&& rg, const Allocator& = Allocator());
```

11 Effects: Constructs a list object with the elements of the range rg.

12 Complexity: Linear in ranges::distance(rg).

### 24.3.10.3 Capacity

```cpp
§ 24.3.10.3
949
```
void resize(size_type sz);

Preconditions: T is Cpp17DefaultInsertable into *this.

Effects: If size() < sz, appends sz - size() default-inserted elements to the sequence. If sz <= size(), equivalent to:

list<T>::iterator it = begin();
advance(it, sz);
erase(it, end());

void resize(size_type sz, const T& c);

Preconditions: T is Cpp17CopyInsertable into *this.

Effects: As if by:

if (sz > size())
  insert(end(), sz-size(), c);
else if (sz < size()) {
  iterator i = begin();
  advance(i, sz);
  erase(i, end());
} else
  // do nothing

24.3.10.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
  iterator insert(const_iterator position, InputIterator first,
                 InputIterator last);
template<container-compatible-range<T> R>
  iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
  void prepend_range(R&& rg);
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
  void append_range(R&& rg);

Complexity: Insertion of a single element into a list takes constant time and exactly one call to a constructor of T. Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor or move constructor of T is exactly equal to the number of elements inserted.

Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);

void pop_front();
void pop_back();
void clear() noexcept;

Effects: Invalidates only the iterators and references to the erased elements.

Throws: Nothing.
Complexity: Erasing a single element is a constant time operation with a single call to the destructor of T. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type T is exactly equal to the size of the range.

24.3.10.5 Operations

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them. In this subclause, arguments for a template parameter named Predicate or BinaryPredicate shall meet the corresponding requirements in 27.2. The semantics of i + n and i - n, where i is an iterator into the list and n is an integer, are the same as those of next(i, n) and prev(i, n), respectively. For merge and sort, the definitions and requirements in 27.8 apply.

list provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if get_allocator() != x.get_allocator().

void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);

Preconditions: addressof(x) != this is true.

Effects: Inserts the contents of x before position and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);

Preconditions: i is a valid dereferenceable iterator of x.

Effects: Inserts an element pointed to by i from list x before position and removes the element from x. The result is unchanged if position == i or position == ++i. Pointers and references to *i continue to refer to this same element but as a member of *this. Iterators to *i (including i itself) continue to refer to the same element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

Preconditions: [first, last) is a valid range in x. position is not an iterator in the range [first, last).

Effects: Inserts elements in the range [first, last) before position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time if addressof(x) == this; otherwise, linear time.

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

Effects: Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by *i == value or pred(*i) != false.

209) As specified in 16.4.4.6, the requirements in this Clause apply only to lists whose allocators compare equal.
Complexity: Exactly \texttt{size()} applications of the corresponding predicate.

Remarks: Stable (16.4.6.8).

\begin{verbatim}
size_type unique();

\end{verbatim}

Let \texttt{binary\_pred} be \texttt{equal\_to\{} for the first overload.

Preconditions: \texttt{binary\_pred} is an equivalence relation.

Effects: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator \texttt{i} in the range \texttt{[begin() + 1, end())} for which \texttt{binary\_pred(*i, *(i - 1))} is \texttt{true}. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the predicate.

Complexity: If \texttt{empty()} is \texttt{false}, exactly \texttt{size()} - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

\begin{verbatim}
void merge(list& x);
void merge(list&& x);

\end{verbatim}

Let \texttt{comp} be \texttt{less\<>} for the first two overloads.

Preconditions: \texttt{*this} and \texttt{x} are both sorted with respect to the comparator \texttt{comp}, and \texttt{get\_allocator()} == \texttt{x.get\_allocator()} is \texttt{true}.

Effects: If \texttt{addressof(x) == this}, there are no effects. Otherwise, merges the two sorted ranges \texttt{[begin(), end())} and \texttt{[x.begin(), x.end())}. The result is a range that is sorted with respect to the comparator \texttt{comp}. Pointers and references to the moved elements of \texttt{x} now refer to those same elements but as members of \texttt{*this}. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \texttt{*this}, not into \texttt{x}.

Complexity: At most \texttt{size()} + \texttt{x.size()} - 1 comparisons if \texttt{addressof(x) != this}; otherwise, no comparisons are performed.

Remarks: Stable (16.4.6.8). If \texttt{addressof(x) != this}, \texttt{x} is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison there are no effects.

\begin{verbatim}
void reverse() noexcept;

\end{verbatim}

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

\begin{verbatim}
void sort();

\end{verbatim}

Effects: Sorts the list according to the \texttt{operator\<} or a \texttt{Compare} function object. If an exception is thrown, the order of the elements in \texttt{*this} is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately \(N \log N\) comparisons, where \(N == \texttt{size()}\).

Remarks: Stable (16.4.6.8).

\section*{24.3.10.6 Erasure [list.erasure]}

\begin{verbatim}
template<class T, class Allocator, class U>

\end{verbatim}

\begin{verbatim}
typename list\<T, Allocator\>::size\_type erase(list\<T, Allocator\>& c, const U& value);

\end{verbatim}

Effects: Equivalent to: \begin{verbatim}return erase\_if(c, [&] (auto& elem) { return elem == value; });\end{verbatim}
template<class T, class Allocator, class Predicate>
    typename list<T, Allocator>::size_type
    erase_if(list<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: return c.remove_if(pred);

### 24.3.11 Class template vector

#### [vector]

#### 24.3.11.1 Overview

A **vector** is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A **vector** meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of a sequence container, including most of the optional sequence container requirements (24.2.4), and, for an element type other than `bool`, of a contiguous container (24.2.2.2). The exceptions are the push_front, prepend_range, pop_front, and emplace_front member functions, which are not provided. Descriptions are provided here only for operations on vector that are not described in one of these tables or for operations where there is additional semantic information.

The types iterator and const_iterator meet the constexpr iterator requirements (25.3.1).

namespace std {
    template<class T, class Allocator = allocator<T>>
    class vector {
        public:
            // types
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 24.2
            using difference_type = implementation-defined; // see 24.2
            using iterator = implementation-defined; // see 24.2
            using const_iterator = implementation-defined; // see 24.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;
            for 24.3.11.2, construct/copy/destroy
            constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
            constexpr explicit vector(const Allocator&) noexcept;
            constexpr vector(size_type n, const Allocator& = Allocator());
            constexpr vector(const T& value, const Allocator& = Allocator());
            template<class InputIterator>
                constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
            template<container-compatible-range<T> R>
                constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
            constexpr vector(const vector& x);
            constexpr vector(vector&&) noexcept;
            constexpr vector(const vector&, const type_identity_t<Allocator>&);
            constexpr vector(vector&&, const type_identity_t<Allocator>&);
            constexpr vector(initializer_list<T>, const Allocator& = Allocator());
            constexpr ~vector();
            constexpr vector& operator=(const vector& x);
            constexpr vector& operator=(vector&& x);
            constexpr vector& operator=(vector& x);
            constexpr vector& operator=(const vector require_allocator_move_assignment::value || allocator_traits<Allocator>::is_always_equal::value));
            constexpr vector& operator=(initializer_list<T>);
            template<Class InputIterator>
                constexpr void assign(InputIterator first, InputIterator last);
            template<container-compatible-range<T> R>
                constexpr void assign_range(R&& rg);
            constexpr void assign(size_type n, const T& u);
            constexpr void assign(initializer_list<T>);

§ 24.3.11.1
constexpr allocator_type get_allocator() const noexcept;

constexpr const_reverse_iterator rend() const noexcept;
constexpr const_iterator cbegin() const noexcept;
constexpr const_iterator cend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// 24.3.11.3, capacity
[[nodiscard]] constexpr bool empty() const noexcept;
constexpr size_type size() const noexcept;
constexpr size_type max_size() const noexcept;
constexpr size_type capacity() const noexcept;
constexpr void resize(size_type sz);
constexpr void resize(size_type sz, const T& c);
constexpr void reserve(size_type n);
constexpr void shrink_to_fit();

// element access
constexpr reference operator[](size_type n);
constexpr const_reference operator[](size_type n) const;
constexpr const_reference at(size_type n) const;
constexpr reference at(size_type n);
constexpr reference front();
constexpr const_reference front() const;
constexpr reference back();
constexpr const_reference back() const;

// 24.3.11.4, data access
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

// 24.3.11.5, modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<R> R>
constexpr void append_range(R&& rg);
constexpr void pop_back();
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<R> R>
constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T> il);
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void swap(vector&);

noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
    allocator_traits<Allocator>::is_always_equal::value);
constexpr void clear() noexcept;

```cpp
template<class InputIterator, class Allocator = allocator<iter_value_type<InputIterator>>>
vector(InputIterator, InputIterator, Allocator = Allocator())
-> vector<iter_value_type<InputIterator>, Allocator>;
```
Effects: A directive that informs a vector of a planned change in size, so that it can manage the storage allocation accordingly. After reserve(), capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve(). If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable type, there are no effects.

Throws: length_error if \( n > \text{max(size())} \).

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

[Note 1: If no reallocation happens, they remain valid. — end note]

No reallocation shall take place during insertions that happen after a call to reserve() until an insertion would make the size of the vector greater than the value of capacity().

```cpp
constexpr void shrink_to_fit();
```

Preconditions: T is Cpp17MoveInsertable into *this.

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size().

[Note 2: The request is non-binding to allow latitude for implementation-specific optimizations. — end note]

It does not increase capacity(), but may reduce capacity() by causing reallocation. If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.

Complexity: If reallocation happens, linear in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator.

[Note 3: If no reallocation happens, they remain valid. — end note]

```cpp
constexpr void swap(vector& x) noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value ||
                                    algorithm_traits<Allocator>::is_always_equal::value);
```

Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.

```cpp
constexpr void resize(size_type sz);
```

Preconditions: T is Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.

Effects: If \( sz < \text{size()} \), erases the last \( \text{size()} - sz \) elements from the sequence. Otherwise, appends \( sz - \text{size()} \) default-inserted elements to the sequence.

Remarks: If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.

```cpp
constexpr void resize(size_type sz, const T& c);
```

Preconditions: T is Cpp17CopyInsertable into *this.

Effects: If \( sz < \text{size()} \), erases the last \( \text{size()} - sz \) elements from the sequence. Otherwise, appends \( sz - \text{size()} \) copies of c to the sequence.

Remarks: If an exception is thrown there are no effects.

### 24.3.11.4 Data

```cpp
constexpr T* data() noexcept;
```

Returns: A pointer such that \( |\text{data()}, \text{data()} + \text{size()}| \) is a valid range. For a non-empty vector, \( \text{data()} == \text{addressof(front())} \) is true.

Complexity: Constant time.

reserves() uses Allocator::allocates() which can throw an appropriate exception.
24.3.11.5 Modifiers

constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
constexpr iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<R>>
constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> constexpr reference emplace_back(Args&&... args);
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr void push_back(const T& x);
constexpr void push_back(T&& x);
template<container-compatible-range<R>>
constexpr void append_range(R&& rg);

Complexity: If reallocation happens, linear in the number of elements of the resulting vector; otherwise, linear in the number of elements inserted plus the distance to the end of the vector.
Remarks: Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. If no reallocation happens, then references, pointers, and iterators before the insertion point remain valid but those at or after the insertion point, including the past-the-end iterator, are invalidated. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T or by any InputIterator operation there are no effects. If an exception is thrown while inserting a single element at the end and T is Cpp17CopyInsertable or is_nothrow_move_constructible_v<T> is true, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void pop_back();

Effects: Invalidates iterators and references at or after the point of the erase.
Remarks: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.
Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

24.3.11.6 Erasure

template<class T, class Allocator, class U>
constexpr typename vector<T, Allocator>::size_type erase(vector<T, Allocator>& c, const U& value);

Effects: Equivalent to:
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

template<class T, class Allocator, class Predicate>
constexpr typename vector<T, Allocator>::size_type erase_if(vector<T, Allocator>& c, Predicate pred);

Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

§ 24.3.11.6
24.3.12 Specialization of vector for bool

24.3.12.1 Partial class template specialization vector<bool, Allocator>

To optimize space allocation, a partial specialization of vector for bool elements is provided:

```cpp
namespace std {
    template<class Allocator>
    class vector<bool, Allocator> {
    public:
        // types
        using value_type = bool;
        using allocator_type = Allocator;
        using pointer = implementation-defined;
        using const_pointer = implementation-defined;
        using const_reference = bool;
        using size_type = implementation-defined; // see 24.2
        using difference_type = implementation-defined; // see 24.2
        using iterator = implementation-defined; // see 24.2
        using const_iterator = implementation-defined; // see 24.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;
    // bit reference
    class reference {
        friend class vector;
        constexpr reference() noexcept;
    public:
        constexpr reference(const reference&) = default;
        constexpr ~reference();
        constexpr operator bool() const noexcept;
        constexpr reference& operator=(bool x) noexcept;
        constexpr reference& operator=(const reference& x) noexcept;

constexpr const_reference at(size_type n) const;
constexpr reference at(size_type n);
constexpr reference front();
constexpr const_reference front() const;
constexpr reference back();
constexpr const_reference back() const;

// modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
void push_back(const bool& x);
<container-compatible-range<R> R> constexpr void append_range(R&& rg);
void pop_back();
 template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
template<class... Args> constexpr iterator insert(const_iterator position, Args&&... args);
template<class... Args> constexpr iterator insert(const_iterator position, size_type n, Args&&... args);
<container-compatible-range<R> R> constexpr iterator insert_range(const_iterator position, R&& rg);
<container-compatible-range<R> R> constexpr iterator insert(const_iterator position, R&& rg);
<container-compatible-range<R> R> constexpr iterator insert(const_iterator position, initializer_list<R> il);

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(vector&);
static constexpr void swap(const_reference x, const_reference y) noexcept;
void flip() noexcept; // flips all bits
void clear() noexcept;

2 Unless described below, all operations have the same requirements and semantics as the primary vector template, except that operations dealing with the bool value type map to bit values in the container storage and allocator_traits::construct (20.2.9.3) is not used to construct these values.
There is no requirement that the data be stored as a contiguous allocation of bool values. A space-optimized representation of bits is recommended instead.

reference is a class that simulates the behavior of references of a single bit in vector<bool>. The conversion function returns true when the bit is set, and false otherwise. The assignment operators set the bit when the argument is (convertible to) true and clear it otherwise. flip reverses the state of the bit.

```cpp
constexpr void flip() noexcept;
```

**Effects**: Replaces each element in the container with its complement.

```cpp
static constexpr void swap(reference x, reference y) noexcept;
```

**Effects**: Exchanges the contents of x and y as if by:

```cpp
bool b = x;
x = y;
y = b;
```

```cpp
template<class Allocator> struct hash<vector<bool, Allocator>>;
```

The specialization is enabled (22.10.19).

```cpp
template<class T>
constexpr bool is-vector-bool-reference = see below;
```

The expression is-vector-bool-reference<T> is true if T denotes the type vector<bool, Alloc>::reference for some type Alloc and vector<bool, Alloc> is not a program-defined specialization.

### 24.3.12.2 Formatter specialization for vector<bool>

```cpp
namespace std {
    template<class T, class charT>
    requires is-vector-bool-reference<T>
    struct formatter<T, charT> {
        private:
            formatter<bool, charT> underlying_; // exposition only

        public:
            template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

            template<class FormatContext>
            typename FormatContext::iterator
            format(const T& ref, FormatContext& ctx) const;
    }
}
```

```cpp
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

Equivalent to: return underlying_.parse(ctx);

```cpp
template<class FormatContext>
typename FormatContext::iterator
format(const T& ref, FormatContext& ctx) const;
```

Equivalent to: return underlying_.format(ref, ctx);

### 24.4 Associative containers

#### 24.4.1 In general

The header <map> defines the class templates map and multimap; the header <set> defines the class templates set and multiset.

The following exposition-only alias templates may appear in deduction guides for associative containers:
template<class InputIterator>
using iter-value-type =
typename iterator_traits<InputIterator>::value_type; // exposition only

template<class InputIterator>
using iter-key-type = remove_const_t<
tuple_element_t<0, iter-value-type<InputIterator>>>>;

template<class InputIterator>
using iter-mapped-type =
tuple_element_t<1, iter-value-type<InputIterator>>>;

template<class InputIterator>
using iter-to-alloc-type =
pair<
add_const_t<tuple_element_t<0, iter-value-type<InputIterator>>>>,
tuple_element_t<1, iter-value-type<InputIterator>>>;

template<ranges::input_range Range>
using range-key-type =
remove_const_t<typename ranges::range_value_t<Range>::first_type>; // exposition only

template<ranges::input_range Range>
using range-mapped-type = typename ranges::range_value_t<Range>::second_type; // exposition only

template<ranges::input_range Range>
using range-to-alloc-type =
pair<add_const_t<typename ranges::range_value_t<Range>::first_type>,
type_name ranges::range_value_t<Range>::second_type>; // exposition only

24.4.2 Header <map> synopsis

#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {

    // 24.4.4, class template map
    template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    class map;

template<class Key, class T, class Compare, class Allocator>
bool operator==(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
synth-three-way-result
    <pair<const Key, T>>
    operator<=>(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
void swap(map<Key, T, Compare, Allocator>& x,
    map<Key, T, Compare, Allocator>& y) noexcept(noexcept(x.swap(y)));

    // 24.4.5, erasure for map
    template<class Key, class T, class Compare, class Allocator, class Predicate>
    typename map<Key, T, Compare, Allocator>::size_type
    erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);

    // 24.4.5, class template multimap
    template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    class multimap;

template<class Key, class T, class Compare, class Allocator>
bool operator==(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
synth-three-way-result
    <pair<const Key, T>>
    operator<=>(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);

§ 24.4.2
template<class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x, 
multimap<Key, T, Compare, Allocator>& y)
nexport(noexport(x.swap(y)));

// §24.4.5.4. erasure for multimap
template<class Key, class T, class Compare, class Allocator, class Predicate>
typename multimap<Key, T, Compare, Allocator>::size_type
erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

namespace pmr {
  template<class Key, class T, class Compare = less<Key>>

    using multiset = std::multiset<Key, Compare, polymorphic_allocator<Key>>;
}

24.4.4 Class template map

24.4.4.1 Overview

1 A map is an associative container that supports unique keys (i.e., contains at most one of each key value) and
provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional
iterators.

2 A map meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an
allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A map also provides most
operations described in 24.2.7 for unique keys. This means that a map supports the a_uniq operations in 24.2.7
but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>.
Descriptions are provided here only for operations on map that are not described in one of those
tables or for operations where there is additional semantic information.

namespace std {
    template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    class map {
    public:
        // types
        using key_type = Key;
        using mapped_type = T;
        using value_type = pair<const Key, T>;
        using key_compare = Compare;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 24.2
        using difference_type = implementation-defined; // see 24.2
        using iterator = implementation-defined; // see 24.2

24.4.4.2 Constructors, copy, and assignment

§ 24.4.4.2 966
explicit map(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator.

Complexity: Constant.

template<class InputIterator>
map(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted with respect to comp and otherwise N log N, where N is last - first.

template<container-compatible-range<value_type> R>
map(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range rg.

Complexity: Linear in N if rg is already sorted with respect to comp and otherwise N log N, where N is ranges::distance(rg).

24.4.4.3 Element access

mapped_type& operator[](const key_type& x);

Effects: Equivalent to: return try_emplace(x).first->second;

mapped_type& operator[](key_type&& x);

Effects: Equivalent to: return try_emplace(std::move(x)).first->second;

template<class K> mapped_type& operator[](K&& x);

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

Effects: Equivalent to: return try_emplace(std::forward<K>(x)).first->second;

mapped_type& at(const key_type& x);

Returns: A reference to the mapped_type corresponding to x in *this.

Throws: An exception object of type out_of_range if no such element is present.

Complexity: Logarithmic.

template<class K> mapped_type& at(const K& x);

template<class K> const mapped_type& at(const K& x) const;

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

Preconditions: The expression find(x) is well-formed and has well-defined behavior.

Returns: A reference to find(x)->second.

Throws: An exception object of type out_of_range if find(x) == end() is true.

Complexity: Logarithmic.

24.4.4.4 Modifiers

template<class P>
pair<iterator, bool> insert(P&& x);

template<class P>
iterator insert(const_iterator position, P&& x);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).
template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class K, class... Args>
pair<iterator, bool> try_emplace(K&& k, Args&&... args);

template<class K, class... Args>
iterator try_emplace(const_iterator hint, K&& k, Args&&... args);

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type. For the first overload, is_convertible_v<K&&, const_iterator> and is_convertible_v<K&&, iterator> are both false.

Preconditions: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise, let r be equal_range(k). Constructs an object u of type value_type with piecewise_construct, forward_as_tuple(std::forward<K>(k)), forward_as_tuple(std::forward<Args>(args)...). If equal_range(u.first) == r is false, the behavior is undefined. Inserts u into *this.

Returns: For the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&?, M&&> is true.

Preconditions: value_type is Cpp17EmplaceConstructible into map from k, std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.
20  Complexity: The same as emplace and emplace_hint, respectively.

    template<class M>
    pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

21  Mandates: \(\text{is\_assignable\_v<!\text{mapped\_type}\&, M&&>\text{ is } \text{true}.}\)

22  Preconditions: value_type is Cpp17EmplaceConstructible into map from std::move(k), std::forward<M>(obj).

23  Effects: If the map already contains an element \(e\) whose key is equivalent to \(k\), assigns std::forward<M>(obj) to \(e\).second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

24  Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \(k\).

25  Complexity: The same as emplace and emplace_hint, respectively.

    template<class K, class M>
    pair<iterator, bool> insert_or_assign(K&& k, M&& obj);

26  Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

27  Mandates: \(\text{is\_assignable\_v<!\text{mapped\_type}\&, M&&>\text{ is } \text{true}.}\)

28  Preconditions: value_type is Cpp17EmplaceConstructible into map from std::forward<K>(k), std::forward<M>(obj).

29  Effects: If the map already contains an element \(e\) whose key is equivalent to \(k\), assigns std::forward<M>(obj) to \(e\).second. Otherwise, let \(r\) be equal_range(k), Constructs an object \(u\) of type value_type with std::forward<K>(k), std::forward<M>(obj). If equal_range(u.first) \(!= r\) is false, the behavior is undefined. Inserts \(u\) into \(*this\).

30  Returns: For the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \(k\).

31  Complexity: The same as emplace and emplace_hint, respectively.

24.4.4.5 Erasure [map.erasure]

    template<class Key, class T, class Compare, class Allocator, class Predicate>
    typename map<Key, T, Compare, Allocator>::size_type
    erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);

1  Effects: Equivalent to:

   auto original_size = c.size();
   for (auto i = c.begin(), last = c.end(); i != last; ) {
     if (pred(*i)) {
       i = c.erase(i);
     } else {
     ++i;
   }
   return original_size - c.size();

24.4.5 Class template multimap [multimap]

24.4.5.1 Overview [multimap.overview]

1  A multimap is an associative container that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type T based on the keys. The multimap class supports bidirectional iterators.

2  A multimap meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A multimap also provides most operations described in 24.2.7 for equal keys. This means that a multimap supports the a_eq operations

§ 24.4.5.1
in 24.2.7 but not the a_uniq operations. For a multimap<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {
    template<class Key, class T, class Compare = less<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class multimap {
    public:
      // types
      using key_type = Key;
      using mapped_type = T;
      using value_type = pair<const Key, T>;
      using key_compare = Compare;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;

  -> multimap<Key, T, less<Key>, Allocator>;

24.4.5.2 Constructors [multimap.cons]

explicit multimap(const Compare& comp, const Allocator& = Allocator());
1  Effects: Constructs an empty multimap using the specified comparison object and allocator.
2  Complexity: Constant.

template<class InputIterator>
multimap(InputIterator first, InputIterator last,
  const Compare& comp = Compare(),
  const Allocator& = Allocator());
3  Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts
   elements from the range [first, last).
4  Complexity: Linear in N if the range [first, last) is already sorted with respect to comp and otherwise
   N log N, where N is last - first.

template<container-compatible-range<value_type> R>
multimap(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
5  Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts
   elements from the range rg.
6  Complexity: Linear in N if rg is already sorted with respect to comp and otherwise N log N, where N is
   ranges::distance(rg).

24.4.5.3 Modifiers [multimap.modifiers]

template<class P> iterator insert(P&& x);
1  template<class P> iterator insert(const_iterator position, P&& x);
2    Constraints: is_constructible_v<value_type, P&&> is true.
3    Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is
   equivalent to return emplace_hint(position, std::forward<P>(x)).

24.4.5.4 Erasure [multimap.erosion]

template<class Key, class T, class Compare, class Allocator, class Predicate>
typename multimap<Key, T, Compare, Allocator>::size_type
erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);
1  Effects: Equivalent to:
   auto original_size = c.size();
   for (auto i = c.begin(), last = c.end(); i != last; ) {
     if (pred(*i)) {
       i = c.erase(i);
     } else {
       ++i;
     }
   }
   return original_size - c.size();

24.4.6 Class template set [set]
24.4.6.1 Overview [set.overview]
1  A set is an associative container that supports unique keys (i.e., contains at most one of each key value) and
   provides for fast retrieval of the keys themselves. The set class supports bidirectional iterators.
A set meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A set also provides most operations described in 24.2.7 for unique keys. This means that a set supports the a_uniq operations in 24.2.7 but not the a_eq operations. For a set<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on set that are not described in one of these tables and for operations where there is additional semantic information.

namespace std {
    template<class Key, class Compare = less<Key>,
             class Allocator = allocator<Key>>
    class set {
    public:
        // types
        using key_type = Key;
        using key_compare = Compare;
        using value_type = Key;
        using value_compare = Compare;
        using allocator_type = Allocator;

const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;

// 24.4.6.4, modifiers
template<class... Args> pair<iterator, bool> emplace(Args&&... args);
template<class... Args> iterator emplace_hint(const_iterator position, Args&&... args);
pair<iterator, bool> insert(const value_type& x);
pair<iterator, bool> insert(value_type&& x);
template<class K> pair<iterator, bool> insert(K&& x);

iterator insert(const_iterator position, const value_type& x);
iterator insert(const_iterator position, value_type&& x);
template<class K> iterator insert(const_iterator position, K&& x);

template<class InputIterator>
void insert(InputIterator first, InputIterator last);
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);
void insert(initializer_list<value_type>);

node_type extract(const_iterator position);
node_type extract(const key_type& x);
template<class K> node_type extract(K&& x);

template<class C2>
void merge(set<Key, C2, Allocator>& source);
template<class C2>
void merge(set<Key, C2, Allocator>&& source);
template<class C2>
void merge(multiset<Key, C2, Allocator>& source);
template<class C2>
void merge(multiset<Key, C2, Allocator>&& source);

// observers
key_compare key_comp() const;
value_compare value_comp() const;
24.4.6.2 Constructors, copy, and assignment

```cpp
explicit set(const Compare& comp, const Allocator& = Allocator());
```

**Effects:** Constructs an empty `set` using the specified comparison object and allocator.
Complexity: Constant.

```cpp
template<class InputIterator>
set(InputIterator first, InputIterator last,
   const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.

Complexity: Linear in `N` if the range `[first, last)` is already sorted with respect to `comp` and otherwise `N \log N`, where `N` is `last - first`.

```cpp
template<container-compatible-range<value_type> R>
set(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

Effects: Constructs an empty `set` using the specified comparison object and allocator, and inserts elements from the range `rg`.

Complexity: Linear in `N` if `rg` is already sorted with respect to `comp` and otherwise `N \log N`, where `N` is `ranges::distance(rg)`.

24.4.6.3 Erasure

```cpp
template<class Key, class Compare, class Allocator, class Predicate>
typename set<Key, Compare, Allocator>::size_type
erase_if(set<Key, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```cpp
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.4.6.4 Modifiers

```cpp
template<class K> pair<iterator, bool> insert(K&& x);
template<class K> iterator insert(const_iterator hint, K&& x);
```

Constraints: The qualified-id `Compare::is_transparent` is valid and denotes a type. For the second overload, `is_convertible_v<K&&, const_iterator>` and `is_convertible_v<K&&, iterator>` are both `false`.

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into `set` from `std::forward<K>(x)`.

Effects: If the set already contains an element that is equivalent to `x`, there is no effect. Otherwise, let `r` be `equal_range(x)`. Constructs an object `u` of type `value_type` with `std::forward<K>(x)`. If `equal_range(u) == r` is `false`, the behavior is undefined. Inserts `u` into `*this`.

Returns: For the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the set element that is equivalent to `x`.

Complexity: Logarithmic.

24.4.7 Class template multiset

24.4.7.1 Overview

A `multiset` is an associative container that supports equivalent keys (i.e., possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The `multiset` class supports bidirectional iterators.

A `multiset` meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of an associative container (24.2.7). `multiset` also provides most operations described in 24.2.7 for duplicate keys. This means that a `multiset` supports the `a_eq` operations in 24.2.7 but not the `a_uniq` operations. For a `multiset<Key>` both the `key_type` and `value_type` are `Key`.

§ 24.4.7.1
Descriptions are provided here only for operations on `multiset` that are not described in one of these tables and for operations where there is additional semantic information.

```cpp
namespace std {
  template<class Key, class Compare = less<Key>,
           class Allocator = allocator<Key>>
  class multiset {
  public:

template<class Key, class Allocator>
multiset(initializer_list<Key>, Allocator) -> multiset<Key, less<Key>, Allocator>;
}
const Compare& comp = Compare(), const Allocator& = Allocator();

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range \([first, last)\).

Complexity: Linear in \(N\) if the range \([first, last)\) is already sorted with respect to \(comp\) and otherwise \(N \log N\), where \(N\) is \(last - first\).

template<container-compatible-range<typename value_type> R>
multiset(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range \(rg\).

Complexity: Linear in \(N\) if \(rg\) is already sorted with respect to \(comp\) and otherwise \(N \log N\), where \(N\) is \(ranges::distance(rg)\).

24.4.7.3 Erasure

template<class Key, class Compare, class Allocator, class Predicate>
typename multiset<Key, Compare, Allocator>::size_type
erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);

Effects: Equivalent to:

```cpp
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

24.5 Unordered associative containers

24.5.1 In general

The header \(<\text{unordered}\_\text{map}>\) defines the class templates \(\text{unordered}\_\text{map}\) and \(\text{unordered}\_\text{multimap}\); the header \(<\text{unordered}\_\text{set}>\) defines the class templates \(\text{unordered}\_\text{set}\) and \(\text{unordered}\_\text{multiset}\).

The exposition-only alias templates \(\text{iter-value-type}, \text{iter-key-type}, \text{iter-mapped-type}, \text{iter-to-alloc-type}, \text{range-key-type}, \text{range-mapped-type}, \) and \(\text{range-to-alloc-type}\) defined in 24.4.1 may appear in deduction guides for unordered containers.

24.5.2 Header \(<\text{unordered}\_\text{map}>\) synopsis

```cpp
#include <compare>    // see 17.11.1
#include <initializer_list>    // see 17.10.2

namespace std {

  // 24.5.4, class template unordered_map
template<class Key, class T, class Hash = hash<Key>, class Pred = equal_to<Key>, class Alloc = allocator<pair<const Key, T>>>
class unordered_map;

  // 24.5.5, class template unordered_multimap
template<class Key, class T, class Hash = hash<Key>, class Pred = equal_to<Key>, class Alloc = allocator<pair<const Key, T>>>
class unordered_multimap;

24.5.4 Class template unordered_map
24.5.4.1 Overview

1 An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

2 An unordered_map meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_unique operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key_type is Key, the mapped_type is T, and the value_type is pair<const Key, T>.

3 Subclause 24.5.4 only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.

§ 24.5.4.1 983
namespace std {
  template<class Key, 
    class T, 
    class Hash = hash<Key>,

1 A `size_type` parameter type in an `unordered_map` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

### 24.5.4.2 Constructors

#### 24.5.4.2.1 `unordered_map()` : `unordered_map(size_type(see below))` { }

##### Effects:

Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

##### Complexity:

Constant.

```cpp
template<class InputIterator>
unordered_map<InputIterator, 1, size_type n, 
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

template<container-compatible-range<value_type> R>
unordered_map<from_range_t, R&& rg,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
```
unordered_map(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

**Effects:** Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range \([f, l]\), \(rg\), or \(il\), respectively. max_load_factor() returns 1.0.

**Complexity:** Average case linear, worst case quadratic.

### 24.5.4.3 Element access

mapped_type& operator[](const key_type& k);

**Effects:** Equivalent to: return try_emplace(k).first->second;

mapped_type& operator[](key_type&& k);

**Effects:** Equivalent to: return try_emplace(std::move(k)).first->second;

template<class K> mapped_type& operator[](K&& k);

**Constraints:** The qualified-ids Hash::is_transparent and Pred::is_transparent are valid and denote types.

**Effects:** Equivalent to: return try_emplace(std::forward<K>(k)).first->second;

mapped_type& at(const key_type& k);

**Returns:** A reference to \(x\).second, where \(x\) is the (unique) element whose key is equivalent to \(k\).

**Throws:** An exception object of type out_of_range if no such element is present.

template<class K> mapped_type& at(const K& k);

template<class K> const mapped_type& at(const K& k) const;

**Constraints:** The qualified-ids Hash::is_transparent and Pred::is_transparent are valid and denote types.

**Preconditions:** The expression find(k) is well-formed and has well-defined behavior.

**Returns:** A reference to find(k)->second.

**Throws:** An exception object of type out_of_range if find(k) == end() is true.

### 24.5.4.4 Modifiers

template<class P>
pair<iterator, bool> insert(P&& obj);

**Constraints:** is_constructible_v<value_type, P&&> is true.

**Effects:** Equivalent to: return emplace(std::forward<P>(obj));

template<class P>
iterator insert(const_iterator hint, P&& obj);

**Constraints:** is_constructible_v<value_type, P&&> is true.

**Effects:** Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);

**Preconditions:** value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).
Effects: If the map already contains an element whose key is equivalent to \( k \), there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`, `forward_as_tuple(std::forward<Args>(args)...)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
```

```cpp
template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into unordered_map from `piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...)`.

Effects: If the map already contains an element whose key is equivalent to \( k \), there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...)`.

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class K, class... Args>
pair<iterator, bool> try_emplace(K&& k, Args&&... args);
```

```cpp
template<class K, class... Args>
iterator try_emplace(const_iterator hint, K&& k, Args&&... args);
```

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.

Mandates: `isAssignable_v<mapped_type, M&&>` is true.

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.

Effects: If the map already contains an element \( e \) whose key is equivalent to \( k \), assigns `std::forward<M>(obj)` to \( e \). Otherwise inserts an object of type `value_type` constructed with \( k, std::forward<M>(obj) \).

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
```

```cpp
template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

Mandates: `isAssignable_v<mapped_type, M&&>` is true.

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.

Effects: If the map already contains an element \( e \) whose key is equivalent to \( k \), assigns `std::forward<M>(obj)` to \( e \). Otherwise inserts an object of type `value_type` constructed with \( k, std::forward<M>(obj) \).

Returns: In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.
template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from std::move(k), std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class K, class M>
pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);

Constraints: The qualified-ids Hash::is_transparent and Pred::is_transparent are valid and denote types.

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from std::forward<K>(k), std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise, let h be hash_function()(k). Constructs an object u of type value_type with std::forward<K>(k), std::forward<M>(obj). If hash_function()(u.first) != h || contains(u.first) is true, the behavior is undefined. Inserts u into *this.

Returns: For the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

24.5.4.5 Erasure

Erase

template<class K, class T, class H, class P, class A, class Predicate>
typename unordered_map<K, T, H, P, A>::size_type
erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);

Effects: Equivalent to:

auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();

24.5.5 Class template unordered_multimap

24.5.5.1 Overview

An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

An unordered_multimap meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multimap<Key, T> the key_type is Key, the mapped_type is T, and the value_type is pair<const Key, T>.
Subclause 24.5.5 only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template<class Key,
             class T,
             class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
      public:
        // types
        using key_type = Key;
        using mapped_type = T;
        using value_type = pair<const Key, T>;
        using hasher = Hash;
        using key_equal = Pred;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 24.2
        using difference_type = implementation-defined; // see 24.2
        using iterator = implementation-defined; // see 24.2
        using const_iterator = implementation-defined; // see 24.2
        using local_iterator = implementation-defined; // see 24.2
        using const_local_iterator = implementation-defined; // see 24.2
        using node_type = unspecified;

§ 24.5.5.1 995
A `size_type` parameter type in an `unordered_multimap` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

### 24.5.5.2 Constructors

- `unordered_multimap() : unordered_multimap(size_type(see below)) { }`
- `explicit unordered_multimap(size_type n, const hasher& hf = hasher(), const key_equal& eql = key_equal(), const allocator_type& a = allocator_type());`

**Effects:** Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

**Complexity:** Constant.

- `unordered_multimap(InputIterator f, InputIterator l, size_type n = see below, const hasher& hf = hasher(), const key_equal& eql = key_equal(), const allocator_type& a = allocator_type());`
- `unordered_multimap(container-compatible-range<value_type> R)`
- `unordered_multimap(initializer_list<value_type> il, size_type n = see below, const hasher& hf = hasher(), const key_equal& eql = key_equal(), const allocator_type& a = allocator_type());`

**Effects:** Constructs an empty `unordered_multimap` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

**Complexity:** Average case linear, worst case quadratic.

### 24.5.5.3 Modifiers

- `template<class P>
  iterator insert(P& obj);`

  **Constraints:** `is_constructible_v<value_type, P&>` is true.

  **Effects:** Equivalent to: return `emplace(std::forward<P>(obj));`

- `template<class P>
  iterator insert(const_iterator hint, P& obj);`

  **Constraints:** `is_constructible_v<value_type, P&>` is true.

  **Effects:** Equivalent to: return `emplace_hint(hint, std::forward<P>(obj));`
24.5.5.4 Erasure

```
template<class K, class T, class H, class P, class A, class Predicate>
    typename unordered_multimap<K, T, H, P, A>::size_type
        erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);
```

Effects: Equivalent to:

```
    auto original_size = c.size();
    for (auto i = c.begin(), last = c.end(); i != last; ) {
        if (pred(*i)) {
            i = c.erase(i);
        } else {
            ++i;
        }
    }
    return original_size - c.size();
```

24.5.6 Class template unordered_set

24.5.6.1 Overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements’ keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a uniq operations in that table, not the a eq operations. For an unordered_set<Key> the key_type and the value_type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.6 only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

```c++
namespace std {
    template<class Key,
             class Hash = hash<Key>,

4 A `size_type` parameter type in an `unordered_set` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

24.5.6.2 Constructors

```c++
unordered_set() : unordered_set(size_type(see below)) { }
explicit unordered_set(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

Effects: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

Complexity: Constant.
```

```c++
template<container-compatible-range<value_type> R>
unordered_multiset(from_range_t, R&& rg,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

unordered_set(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());
```

Effects: Constructs an empty `unordered_set` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. If `n` is not provided, the number of buckets is implementation-defined. Then inserts elements from the range `[f, l)`, `rg`, or `il`, respectively. `max_load_factor()` returns 1.0.

Complexity: Average case linear, worst case quadratic.
24.5.6.3 Erasure

```cpp
template<class K, class H, class P, class A, class Predicate>
typename unordered_set<K, H, P, A>::size_type
erase_if(unordered_set<K, H, P, A>& c, Predicate pred);
```

**Effects:** Equivalent to:

```cpp
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.5.6.4 Modifiers

```cpp
template<class K> pair<iterator, bool> insert(K&& obj);
template<class K> iterator insert(const_iterator hint, K&& obj);
```

**Constraints:** The qualified-ids Hash::is_transparent and Pred::is_transparent are valid and denote types. For the second overload, is_convertible_v<K&&, const_iterator> and is_convertible_v<K&&, iterator> are both false.

**Preconditions:** `value_type` is `Cpp17EmplaceConstructible` into `unordered_set` from `std::forward<K>(obj)`.

**Effects:** If the set already contains an element that is equivalent to `obj`, there is no effect. Otherwise, let `h` be `hash_function()`(`obj`). Constructs an object `u` of type `value_type` with `std::forward<K>(obj)`. If `hash_function()`(`u`) != `h || contains(u)` is true, the behavior is undefined. Inserts `u` into `*this`.

**Returns:** For the first overload, the `bool` component of the returned pair is true if and only if the insertion took place. The returned iterator points to the set element that is equivalent to `obj`.

**Complexity:** Average case constant, worst case linear.

24.5.7 Class template unordered_multiset

24.5.7.1 Overview

An `unordered_multiset` is an unordered associative container that supports equivalent keys (an instance of `unordered_multiset` may contain multiple copies of the same key value) and in which each element’s key is the element itself. The `unordered_multiset` class supports forward iterators.

An `unordered_multiset` meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an `unordered_multiset` supports the `a_eq` operations in that table, not the `a_uniq` operations. For an `unordered_multiset<Key>` the `key_type` and the `value_type` are both `Key`. The `iterator` and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.7 only describes operations on `unordered_multiset` that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template<class Key, 
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Allocator = allocator<Key>>
    class unordered_multiset {
        public:
            // types
            using key_type = Key;
            using value_type = Key;
            using hasher = Hash;
            using key_equal = Pred;
    }
}
```

    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

1 Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

2 Complexity: Constant.
const allocator_type& a = allocator_type();

template<container-compatible-range <value_type> R>
unordered_multiset(from_range_t, R&& rg,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

unordered_multiset(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l), rg, or il, respectively. max_load factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.7.3 Erasure

template<class K, class H, class P, class A, class Predicate>
typename unordered_multiset<K, H, P, A>::size_type
erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);

Effects: Equivalent to:

```cpp
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

24.6 Container adaptors

24.6.1 In general

The headers <queue>, <stack>, <flat_map>, and <flat_set> define the container adaptors queue and priority_queue, stack, flat_map and flat_multimap, and flat_set and flat_multiset, respectively.

Each container adaptor takes one or more template parameters named Container, KeyContainer, or MappedContainer that denote the types of containers that the container adaptor adapts. Each container adaptor has at least one constructor that takes a reference argument to one or more such template parameters. For each constructor reference argument to a container C, the constructor copies the container into the container adaptor. If C takes an allocator, then a compatible allocator may be passed in to the adaptor’s constructor. Otherwise, normal copy or move construction is used for the container argument. For the container adaptors that take a single container template parameter Container, the first template parameter T of the container adaptor shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor’s Container, KeyContainer, MappedContainer, or Compare object (if any).

A constructor template of a container adaptor shall not participate in overload resolution if it has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

For container adaptors that have them, the insert, emplace, and erase members affect the validity of iterators, references, and pointers to the adaptor’s container(s) in the same way that the containers’ respective insert, emplace, and erase members do.

Example 1: A call to flat_map<Key, T>::insert can invalidate all iterators to the flat_map. — end example]
A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

- It has a `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has a `Container`, `KeyContainer`, or `MappedContainer` template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has no `Container`, `KeyContainer`, or `MappedContainer` template parameter, and it has an `Allocator` template parameter, and a type that does not qualify as an allocator is deduced for that parameter.
- It has both `Container` and `Allocator` template parameters, and `uses_allocator_v<Container, Allocator>` is false.
- It has both `KeyContainer` and `Allocator` template parameters, and `uses_allocator_v<KeyContainer, Allocator>` is false.
- It has both `KeyContainer` and `Compare` template parameters, and `is_invocable_v<const Compare&, const typename KeyContainer::value_type&, const typename KeyContainer::value_type&>` is not a valid expression or is false.
- It has both `MappedContainer` and `Allocator` template parameters, and `uses_allocator_v<MappedContainer, Allocator>` is false.

The exposition-only alias template `iter-value-type` defined in 24.3.1 and the exposition-only alias templates `iter-key-type`, `iter-mapped-type`, `range-key-type`, and `range-mapped-type` defined in 24.4.1 may appear in deduction guides for container adaptors.

The following exposition-only alias template may appear in deduction guides for container adaptors:

```
template<class Allocator, class T>
using alloc_rebind =                     // exposition only
    typename allocator_traits<Allocator>::template rebind_alloc<T>;
```

### 24.6.2 Header `<queue>` synopsis

```
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2

namespace std {
    // 24.6.6, class template queue
    template<class T, class Container = deque<T>> class queue;

    template<class T, class Container>
    bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>
    bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>

24.6.6 Class template queue

24.6.6.1 Definition

Any sequence container supporting operations front(), back(), push_back() and pop_front() can be used to instantiate queue. In particular, list (24.3.10) and deque (24.3.8) can be used.

namespace std {
   template<class T, class Container = deque<T>>
   class queue {
      public:
         using value_type = typename Container::value_type;
         using reference = typename Container::reference;
         using const_reference = typename Container::const_reference;
         using size_type = typename Container::size_type;
         using container_type = Container;

      protected:
         Container c;

      public:
         queue() : queue(Container()) {}
         explicit queue(const Container&);
         explicit queue(Container&&);
         template<class InputIterator> queue(InputIterator first, InputIterator last);
         template<container-compatible-range<T> R> queue(from_range_t, R&& rg);
         template<class Alloc> explicit queue(const Alloc&);
         template<class Alloc> queue(const Container&, const Alloc&);
         template<class Alloc> queue(Container&&, const Alloc&);
         template<class Alloc> queue(const queue&, const Alloc&);
         template<class Alloc> queue(queue&&, const Alloc&);
         template<class InputIterator, class Alloc>
            queue(InputIterator first, InputIterator last, const Alloc&);
         template<container-compatible-range<T> R, class Alloc>
            queue(from_range_t, R&& rg, const Alloc&);

         [[nodiscard]] bool empty() const { return c.empty(); }
         size_type size() const { return c.size(); }
         reference front() { return c.front(); }
         const_reference front() const { return c.front(); }
         reference back() { return c.back(); }
         const_reference back() const { return c.back(); }
         void push(const value_type& x) { c.push_back(x); }
         void push(value_type&& x) { c.push_back(std::move(x)); }
         template<container-compatible-range<T> R> void push_range(R&& rg);
         template<class... Args>
            decltype(auto) emplace(Args&&... args)
               { return c.emplace_back(std::forward<Args>(args)...); }
         void pop() { c.pop_front(); }
         void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
               { using std::swap; swap(c, q.c); }
   };
}

template<class Container>
queue(Container) -> queue<typename Container::value_type, Container>;

template<class InputIterator>
queue(InputIterator, InputIterator) -> queue<iter-value-type<InputIterator>>;
template<ranges::input_range R>
queue(from_range_t, R&&) -> queue<ranges::range_value_t<R>>;

template<class Container, class Allocator>
queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

template<class InputIterator, class Allocator>
queue(InputIterator, InputIterator, Allocator)
-> queue<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>, Allocator>>;

template<ranges::input_range R, class Allocator>
queue(from_range_t, R&&, Allocator)
-> queue<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

template<class T, class Container, class Alloc>
struct uses_allocator<queue<T, Container>, Alloc>
: uses_allocator<Container, Alloc>::type { };

24.6.6.2 Constructors [queue.cons]

explicit queue(const Container& cont);

Effects: Initializes c with cont.

explicit queue(Container&& cont);

Effects: Initializes c with std::move(cont).

template<class InputIterator>
queue(InputIterator first, InputIterator last);

Effects: Initializes c with first as the first argument and last as the second argument.

template<container-compatible-range<T> R>
queue(from_range_t, R&& rg);

Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg)).

24.6.6.3 Constructors with allocators [queue.cons.alloc]

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit queue(const Alloc& a);

Effects: Initializes c with a.

template<class Alloc> queue(const container_type& cont, const Alloc& a);

Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> queue(container_type& cont, const Alloc& a);

Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> queue(queue& q, const Alloc& a);

Effects: Initializes c with q.c as the first argument and a as the second argument.

template<class Alloc> queue(queue&& q, const Alloc& a);

Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument.

template<class InputIterator, class Alloc>
queue(InputIterator first, InputIterator last, const Alloc& alloc);

Effects: Initializes c with first as the first argument, last as the second argument, and alloc as the third argument.
template<container-compatible-range<T> R, class Alloc>
queue(from_range_t, R&& rg, const Alloc& a);

Effects: Initializes \( c \) with ranges::to<Container>(std::forward<R>(rg), a).

### 24.6.6.4 Modifiers

```c
24.6.6.4 Modifiers [queue.mod]
template<container-compatible-range<T> R>
void push_range(R&& rg);
```

Effects: Equivalent to \( c \).append_range(std::forward<R>(rg)) if that is a valid expression, otherwise ranges::copy(rg, back_inserter(c)).

### 24.6.6.5 Operators

```c
24.6.6.5 Operators [queue.ops]
template<class T, class Container>
bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c == y.c \).

template<class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c != y.c \).

template<class T, class Container>
bool operator<(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c < y.c \).

template<class T, class Container>
bool operator>(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c > y.c \).

template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c <= y.c \).

template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c >= y.c \).

template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: \( x.c <=> y.c \).
```

### 24.6.6.6 Specialized algorithms

```c
24.6.6.6 Specialized algorithms [queue.special]
template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: is_swappable_v<Container> is true.

Effects: As if \( x \).swap(y).

### 24.6.7 Class template priority_queue

#### 24.6.7.1 Overview [priqueue.overview]

Any sequence container with random access iterator and supporting operations front(), push_back() and pop_back() can be used to instantiate priority_queue. In particular, vector (24.3.11) and deque (24.3.8) can be used. Instantiating priority_queue also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (27.8).
namespace std {
    template<class T, class Container = vector<T>,
             class Compare = less<typename Container::value_type>>
    class priority_queue {
    public:
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;
        using value_compare = Compare;
    protected:
        Container c;
        Compare comp;
    public:
        priority_queue() : priority_queue(Compare()) {}  
        explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}  
        priority_queue(const Compare& x, const Container&);  
        priority_queue(const Compare& x, Container&&);  
        template<class InputIterator>
        priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());  
        template<class InputIterator>
        priority_queue(InputIterator first, InputIterator last, const Compare& x,  
                        const Container&);  
        template<class InputIterator>
        priority_queue(InputIterator first, InputIterator last, const Compare& x,  
                        Container&&);  
        template<class Alloc> explicit priority_queue(const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, const Container&, const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, Container&&, const Alloc&);  
        template<class Alloc> priority_queue(const priority_queue&, const Alloc&);  
        template<class Alloc> priority_queue(priority_queue&&, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, const Container&,  
                        const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, Container&&,  
                        const Alloc&);  
        template<class Alloc> explicit priority_queue(const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, const Container&, const Alloc&);  
        template<class Alloc> priority_queue(const Compare&, Container&&, const Alloc&);  
        template<class Alloc> priority_queue(const priority_queue&, const Alloc&);  
        template<class Alloc> priority_queue(priority_queue&&, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, const Container&,  
                        const Alloc&);  
        template<class InputIterator, class Alloc>
        priority_queue(InputIterator, InputIterator, const Compare&, Container&&,  
                        const Alloc&);  
        [[nodiscard]] bool empty() const { return c.empty(); }  
        size_type size() const { return c.size(); }  
        const_reference top() const { return c.front(); }

template<
    ranges::input_range R,
    class Compare = less<ranges::range_value_t<R>>,
    class Container = vector<ranges::range_value_t<R>>,
    class Allocator = Container()>
priority_queue(from_range_t, R&&, Compare = Compare(), Container = Container()) -> priority_queue<typename Container::value_type, Container, Compare>;

template<class Compare, class Container, class Allocator>
priority_queue(Compare, Container, Allocator) -> priority_queue<typename Container::value_type, Container, Compare>;

template<class InputIterator, class Allocator>
priority_queue(InputIterator, InputIterator, Allocator) -> priority_queue<typename Container::value_type, Container, Compare>;

24.6.7.2 Constructors [priqueue.cons]

priority_queue(const Compare& x, const Container& y);

Preconditions: x defines a strict weak ordering (27.8).

Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate); calls make_heap(c.begin(), c.end(), comp).

template<
    class InputIterator,
    class Compare = Compare(),
    class Container = Container()>
priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare())

Preconditions: x defines a strict weak ordering (27.8).

Effects: Initializes c with first as the first argument and last as the second argument, and initializes comp with x; then calls make_heap(c.begin(), c.end(), comp).
template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, const Container& y);

template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, Container&& y);

5
Preconditions: x defines a strict weak ordering (27.8).

6
Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate);
calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

template&lt;container-compatible-range&lt;T&gt; R&gt;
    priority_queue(from_range_t, R&& rg, const Compare& x = Compare());

7
Preconditions: x defines a strict weak ordering (27.8).

8
Effects: Initializes comp with x and c with ranges::to&lt;Container&gt;(std::forward&lt;R&gt;(rg)) and finally calls make_heap(c.begin(), c.end(), comp).

24.6.7.3 Constructors with allocators

1 If uses_allocator_v&lt;container_type, Alloc&gt; is false the constructors in this subclause shall not par-
ticipate in overload resolution.

template&lt;class Alloc&gt; explicit priority_queue(const Alloc& a);

2 Effects: Initializes c with a and value-initializes comp.

template&lt;class Alloc&gt; priority_queue(const Compare& compare, const Alloc& a);

3 Effects: Initializes c with a and initializes comp with compare.

template&lt;class Alloc&gt;
    priority_queue(const Compare& compare, const Container& cont, const Alloc& a);

4 Effects: Initializes c with cont as the first argument and a as the second argument, and initializes comp
    with compare; calls make_heap(c.begin(), c.end(), comp).

template&lt;class Alloc&gt;
    priority_queue(const Compare& compare, Container&& cont, const Alloc& a);

5 Effects: Initializes c with std::move(cont) as the first argument and a as the second argument, and
    initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

template&lt;class Alloc&gt; priority_queue(const priority_queue&amp; q, const Alloc& a);

6 Effects: Initializes c with q.c as the first argument and a as the second argument, and initializes comp
    with q.comp.

template&lt;class Alloc&gt; priority_queue(priority_queue&& q, const Alloc& a);

7 Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument, and
    initializes with std::move(q.comp).

template&lt;class InputIterator, class Alloc&gt;
    priority_queue(InputIterator first, InputIterator last, const Alloc& a);

8 Effects: Initializes c with first as the first argument, last as the second argument, and a as the third
    argument, and value-initializes comp; calls make_heap(c.begin(), c.end(), comp).

template&lt;class InputIterator, class Alloc&gt;
    priority_queue(InputIterator first, InputIterator last, const Compare&amp; compare, const Alloc&amp; a);

9 Effects: Initializes c with first as the first argument, last as the second argument, and a as the third
    argument, and initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

template&lt;class InputIterator, class Alloc&gt;
    priority_queue(InputIterator first, InputIterator last, const Compare&amp; compare,
        const Container&amp; cont, const Alloc&amp; a);

10 Effects: Initializes c with cont as the first argument and a as the second argument, and initializes
    comp with compare; calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(),
        c.end(), comp).
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Compare& compare, Container&& cont, const Alloc& a);

**Effects:** Initializes c with std::move(cont) as the first argument and a as the second argument, and initializes comp with compare; calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

```cpp
template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Compare& compare, const Alloc& a);
```

**Effects:** Initializes comp with compare and c with ranges::to<Container>(std::forward<R>(rg), a); calls make_heap(c.begin(), c.end(), comp).

```cpp
template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Alloc& a);
```

**Effects:** Initializes c with ranges::to<Container>(std::forward<R>(rg), a); calls make_heap(c.begin(), c.end(), comp).

### 24.6.7.4 Members

**void push(const value_type& x);**

**Effects:** As if by:
```cpp
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

**Effects:** As if by:
```cpp
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

**template<container-compatible-range<T> R> void push_range(R&& rg);**

**Effects:** Inserts all elements of rg in c via c.append_range(std::forward<R>(rg)) if that is a valid expression, or ranges::copy(rg, back_inserter(c)) otherwise. Then restores the heap property as if by make_heap(c.begin(), c.end(), comp).

**Postconditions:** is_heap(c.begin(), c.end(), comp) is true.

**template<class... Args> void emplace(Args&&... args);**

**Effects:** As if by:
```cpp
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

**Effects:** As if by:
```cpp
c.pop_back();
pop_heap(c.begin(), c.end(), comp);
```

### 24.6.7.5 Specialized algorithms

**template<class T, class Container, class Compare> void swap(priority_queue<T, Container, Compare>& x, priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));**

**Constraints:** is_swappable_v<Container> is true and is_swappable_v<Compare> is true.

**Effects:** As if by x.swap(y).

### 24.6.8 Class template stack

#### 24.6.8.1 General

Any sequence container supporting operations back(), push_back() and pop_back() can be used to instantiate stack. In particular, vector (24.3.11), list (24.3.10) and deque (24.3.8) can be used.
24.6.8.2 Definition

namespace std {
    template<class T, class Container = deque<T>>
    class stack {
    public:
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;

    protected:
        Container c;

    public:
        stack() : stack(Container()) {}
        explicit stack(const Container&);
    
    template<class InputIterator> stack(InputIterator first, InputIterator last);
    template<container-compatible-range<T> R> stack(from_range_t, R&& rg);
    template<class Alloc> explicit stack(const Alloc&);
    template<class Alloc> stack(const Container&, const Alloc&);
    template<class Alloc> stack(Container&&, const Alloc&);
    template<class Alloc> stack(const stack&, const Alloc&);
    template<class Alloc> stack(stack&&, const Alloc&);
    template<class Alloc> stack(InputIterator, class Alloc>
        stack(InputIterator first, InputIterator last, const Alloc&);
    template<container-compatible-range<T> R, class Alloc>
        stack(from_range_t, R&& rg, const Alloc&);

    [[nodiscard]] bool empty() const { return c.empty(); }
    size_type size() const { return c.size(); }
    reference top() { return c.back(); }
    const_reference top() const { return c.back(); }
    void push(const value_type& x) { c.push_back(x); }
    void push(value_type&& x) { c.push_back(std::move(x)); }
    template<container-compatible-range<T> R>
        void push_range(R&& rg);
    template<class... Args>
        decltype(auto) emplace(Args&&... args)
            { return c.emplace_back(std::forward<Args>(args)...); }
    template<class Container>
        stack(Container) -> stack<typename Container::value_type, Container>;
    template<class InputIterator>
        stack(InputIterator, InputIterator) -> stack<iter-value-type<InputIterator>>;
    template<ranges::input_range R>
        stack(from_range_t, R&&) -> stack<ranges::range_value_t<R>>;
    template<class Container, class Allocator>
        stack(Container, Allocator) -> stack<typename Container::value_type, Container>;
    template<class InputIterator, class Allocator>
        stack(InputIterator, InputIterator, Allocator)
            -> stack<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>,
                Allocator>>;

    };
template<ranges::input_range R, class Allocator>
stack(from_range_t, R&&, Allocator)
  -> stack<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

template<class T, class Container, class Alloc>
struct uses_allocator<stack<T, Container>, Alloc>
  : uses_allocator<Container, Alloc>::type { };

24.6.8.3 Constructors

explicit stack(const Container& cont);
  Effects: Initializes c with cont.

explicit stack(Container&& cont);
  Effects: Initializes c with std::move(cont).

template<class InputIterator>
stack(InputIterator first, InputIterator last);
  Effects: Initializes c with first as the first argument and last as the second argument.

template<container-compatible-range<T> R>
stack(from_range_t, R&& rg);
  Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg)).

24.6.8.4 Constructors with allocators

1 If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit stack(const Alloc& a);
  Effects: Initializes c with a.

template<class Alloc> stack(const container_type& cont, const Alloc& a);
  Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> stack(container_type&& cont, const Alloc& a);
  Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> stack(const stack& s, const Alloc& a);
  Effects: Initializes c with s.c as the first argument and a as the second argument.

template<class Alloc> stack(stack&& s, const Alloc& a);
  Effects: Initializes c with std::move(s.c) as the first argument and a as the second argument.

template<class InputIterator, class Alloc>
stack(InputIterator first, InputIterator last, const Alloc& alloc);
  Effects: Initializes c with first as the first argument, last as the second argument, and alloc as the third argument.

template<container-compatible-range<T> R, class Alloc>
stack(from_range_t, R&& rg, const Alloc& alloc);
  Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg), a).

24.6.8.5 Modifiers

template<container-compatible-range<T> R>
void push_range(R&& rg);
  Effects: Equivalent to c.append_range(std::forward<R>(rg)) if that is a valid expression, otherwise ranges::copy(rg, back_inserter(c)).
24.6.8.6 Operators

```cpp
template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c == y.c.
```

```cpp
template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c != y.c.
```

```cpp
template<class T, class Container>
bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c < y.c.
```

```cpp
template<class T, class Container>
bool operator>(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c > y.c.
```

```cpp
template<class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c <= y.c.
```

```cpp
template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c >= y.c.
```

```cpp
template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c <=> y.c.
```

24.6.8.7 Specialized algorithms

```cpp
template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));

Constraints: is_swappable_v<Container> is true.

Effects: As if by x.swap(y).
```

24.6.9 Class template flat_map

24.6.9.1 Overview

A flat_map is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. flat_map supports iterators that meet the Cpp17InputIterator requirements and model the random_access_iterator concept (25.3.4.13).

A flat_map meets all of the requirements of a container (24.2.2.2) and of a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). flat_map meets the requirements of an associative container (24.2.7), except that:

(2.1) it does not meet the requirements related to node handles (24.2.5),
(2.2) it does not meet the requirements related to iterator invalidation, and
(2.3) the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_map does not meet the additional requirements of an allocator-aware container (24.2.2.5). — end note]

A flat_map also provides most operations described in 24.2.7 for unique keys. This means that a flat_map supports the a_uniq operations in 24.2.7 but not the a_eq operations. For a flat_map<Key, T> the key_type is Key and the value_type is pair<Key, T>.
4 Descriptions are provided here only for operations on `flat_map` that are not described in one of those sets of requirements or for operations where there is additional semantic information.

5 A `flat_map` maintains the following invariants:

- it contains the same number of keys and values;
- the keys are sorted with respect to the comparison object; and
- the value at offset `off` within the value container is the value associated with the key at offset `off` within the key container.

6 If any member function in 24.6.9.2 exits via an exception the invariants are restored.

[Note 2: This can result in the `flat_map` being emptied. — end note]

7 Any type `C` that meets the sequence container requirements (24.2.4) can be used to instantiate `flat_map`, as long as `C::iterator` meets the `Cpp17RandomAccessIterator` requirements and invocations of member functions `C::size` and `C::max_size` do not exit via an exception. In particular, `vector` (24.3.11) and `deque` (24.3.8) can be used.

[Note 3: `vector<bool>` is not a sequence container. — end note]

8 The program is ill-formed if `Key` is not the same type as `KeyContainer::value_type` or `T` is not the same type as `MappedContainer::value_type`.

9 The effect of calling a constructor that takes both `key_container_type` and `mapped_container_type` arguments with containers of different sizes is undefined.

10 The effect of calling a constructor or member function that takes a `sorted_unique_t` argument with a container, containers, or range that is not sorted with respect to `key_comp()`, or that contains equal elements, is undefined.

24.6.9.2 Definition

```cpp
namespace std {
    template<class Key, class T, class Compare = less<Key>,
             class KeyContainer = vector<Key>, class MappedContainer = vector<T>>
    class flat_map {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<key_type, mapped_type>;
            using key_compare = Compare;
            using reference = pair<const key_type&, mapped_type&>;
            using const_reference = pair<const key_type&, const mapped_type&>;
            using size_type = size_t;
            using difference_type = ptrdiff_t;
            using iterator = implementation-defined; // see 24.2
            using const_iterator = implementation-defined; // see 24.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;
            using key_container_type = KeyContainer;
            using mapped_container_type = MappedContainer;

            class value_compare {
                private:
                    key_compare comp; // exposition only
                    value_compare(key_compare c) : comp(c) {} // exposition only
                public:
                    bool operator()(const_reference x, const_reference y) const {
                        return comp(x.first, y.first);
                    }
            };

            struct containers {
                key_container_type keys;
                mapped_container_type values;
            }

```

template<class Allocator>
flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont, const key_compare& comp, const Allocator& a);

3 Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

4 Effects: Equivalent to flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

5 Complexity: Same as flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively.

flat_map(sorted_unique_t, key_container_type key_cont, mapped_container_type mapped_cont, const key_compare& comp = key_compare());

6 Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and compare with comp.

7 Complexity: Constant.

template<class Allocator>
flat_map(sorted_unique_t s, const key_container_type& key_cont, const mapped_container_type& mapped_cont, const Allocator& a);

8 Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

9 Effects: Equivalent to flat_map(s, key_cont, mapped_cont) and flat_map(s, key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

10 Complexity: Linear.
template<class Allocator>
    flat_map(sorted_unique_t, initializer_list<value_type> il, const key_compare& comp, const Allocator& a);

template<class Allocator>
    flat_map(sorted_unique_t, initializer_list<value_type> il, const Allocator& a);

**11** Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

**12** Effects: Equivalent to the corresponding non-allocator constructors except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

### 24.6.9.4 Capacity

[size=flat.map.capacity]

```cpp
size_type size() const noexcept;
```

**1** Returns: c.keys.size().

```cpp
size_type max_size() const noexcept;
```

**2** Returns: min<size_type>(c.keys.max_size(), c.values.max_size()).

### 24.6.9.5 Access

[size=flat.map.access]

```cpp
mapped_type& operator[](const key_type& x);
```

**1** Effects: Equivalent to: return try_emplace(x).first->second;

```cpp
mapped_type& operator[](key_type&& x);
```

**2** Effects: Equivalent to: return try_emplace(std::move(x)).first->second;

```cpp
template<class K> mapped_type& operator[](K&& x);
```

**3** Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

**4** Effects: Equivalent to: return try_emplace(std::forward<K>(x)).first->second;

```cpp
mapped_type& at(const key_type& x);
```

**5** Returns: A reference to the mapped_type corresponding to x in *this.

**6** Throws: An exception object of type out_of_range if no such element is present.

**7** Complexity: Logarithmic.

```cpp
template<class K> mapped_type& at(const K& x);
```

```cpp
template<class K> const mapped_type& at(const K& x) const;
```

**8** Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

**9** Preconditions: The expression find(x) is well-formed and has well-defined behavior.

**10** Returns: A reference to the mapped_type corresponding to x in *this.

**11** Throws: An exception object of type out_of_range if no such element is present.

**12** Complexity: Logarithmic.

### 24.6.9.6 Modifiers

[size=flat.map.modifiers]

```cpp
template<class... Args> pair<iterator, bool> emplace(Args&&... args);
```

**1** Constraints: is_constructible_v<pair<key_type, mapped_type>, Args...> is true.

**2** Effects: Initializes an object t of type pair<key_type, mapped_type> with std::forward<Args>(args)...; if the map already contains an element whose key is equivalent to t.first, *this is unchanged. Otherwise, equivalent to:

```cpp
auto key_it = ranges::upper_bound(c.keys, t.first, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::move(t.first));
c.values.insert(value_it, std::move(t.second));
```
Returns: The bool component of the returned pair is true if and only if the insertion took place, and the iterator component of the pair points to the element with key equivalent to t.first.

```cpp
template<class P> pair<iterator, bool> insert(P&& x);
template<class P> iterator insert(const_iterator position, P&& x);
```

Constraints: is_constructible_v<pair<key_type, mapped_type>, P> is true.

Effects: The first form is equivalent to return emplace(std::forward<P>(x));. The second form is equivalent to return emplace_hint(position, std::forward<P>(x));.

```cpp
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to c as if by:
```cpp```
```cpp
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}
```
Then, sorts the range of newly inserted elements with respect to value_comp(); merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:
```cpp```
```cpp
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

Complexity: $N + M \log M$, where $N$ is size() before the operation and $M$ is distance(first, last).

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```cpp
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

Effects: Adds elements to c as if by:
```cpp```
```cpp
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}
```
Then, merges the sorted range of newly added elements and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:
```cpp```
```cpp
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
```

Complexity: Linear in $N$, where $N$ is size() after the operation.

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```cpp
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);
```

Effects: Adds elements to c as if by:
```cpp```
```cpp
for (const auto& e : rg) {
    c.keys.insert(c.keys.end(), e.first);
    c.values.insert(c.values.end(), e.second);
}
```
Then, sorts the range of newly inserted elements with respect to \texttt{value\_comp()}; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases the duplicate elements as if by:

\begin{verbatim}
auto zv = views::zip(c.keys, c.values);
auto it = ranges::unique(zv, key\_equiv(compare)).begin();
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());
\end{verbatim}

\textbf{Complexity:} $N + M \log M$, where $N$ is \texttt{size()} before the operation and $M$ is \texttt{ranges::distance(rg)}.

\textbf{Remarks:} Since this operation performs an in-place merge, it may allocate memory.

\begin{verbatim}
template<class... Args>
pair<
iterator, bool> try\_emplace(const key\_type& k, Args&&... args);
template<class... Args>
pair<
iterator, bool> try\_emplace(key\_type&& k, Args&&... args);
template<class... Args>
iterator try\_emplace(const\_iterator hint, const key\_type& k, Args&&... args);
template<class... Args>
iterator try\_emplace(const\_iterator hint, key\_type&& k, Args&&... args);
\end{verbatim}

\textbf{Constraints:} \texttt{is\_constructible\_v<mapped\_type, Args...>} is true.

\textbf{Effects:} If the map already contains an element whose key is equivalent to \texttt{k}, \*\texttt{this} and \texttt{args...} are unchanged. Otherwise equivalent to:

\begin{verbatim}
auto key\_it = ranges::upper\_bound(c.keys, k, compare);
auto value\_it = c.values.begin() + distance(c.keys.begin(), key\_it);
c.keys.insert(key\_it, std::forward<decltype(k)>(k));
c.values.emplace(value\_it, std::forward<Args>(args)...);
\end{verbatim}

\textbf{Returns:} In the first two overloads, the \texttt{bool} component of the returned pair is \texttt{true} if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \texttt{k}.

\textbf{Complexity:} The same as \texttt{emplace} for the first two overloads, and the same as \texttt{emplace\_hint} for the last two overloads.

\begin{verbatim}
template<class K, class... Args>
pair<
iterator, bool> try\_emplace(K&& k, Args&&... args);
template<class K, class... Args>
iterator try\_emplace(const\_iterator hint, K&& k, Args&&... args);
\end{verbatim}

\textbf{Constraints:}

\begin{enumerate}
\item The \texttt{qualified\_id Compare::is\_transparent} is valid and denotes a type.
\item \texttt{is\_constructible\_v<key\_type, K>} is true.
\item \texttt{is\_constructible\_v<mapped\_type, Args...>} is true.
\item For the first overload, \texttt{is\_convertible\_v<K&&, const\_iterator>} and \texttt{is\_convertible\_v<K&&, iterator>} are both false.
\end{enumerate}

\textbf{Preconditions:} The conversion from \texttt{k} into \texttt{key\_type} constructs an object \texttt{u}, for which \texttt{find(k) == find(u)} is \texttt{true}.

\textbf{Effects:} If the map already contains an element whose key is equivalent to \texttt{k}, \*\texttt{this} and \texttt{args...} are unchanged. Otherwise equivalent to:

\begin{verbatim}
auto key\_it = ranges::upper\_bound(c.keys, k, compare);
auto value\_it = c.values.begin() + distance(c.keys.begin(), key\_it);
c.keys.emplace(key\_it, std::forward<K>(k));
c.values.emplace(value\_it, std::forward<Args>(args)...);
\end{verbatim}

\textbf{Returns:} In the first overload, the \texttt{bool} component of the returned pair is \texttt{true} if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \texttt{k}.

\textbf{Complexity:} The same as \texttt{emplace} and \texttt{emplace\_hint}, respectively.

\begin{verbatim}
template<class M>
pair<
iterator, bool> insert\_or\_assign(const key\_type& k, M&& obj);
\end{verbatim}
template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Constraints: is_assignable_v<mapped_type&, M> is true and is_constructible_v<mapped_type, M> is true.

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise, equivalent to

try_emplace(std::forward<decltype(k)>(k), std::forward<M>(obj))

for the first two overloads or

try_emplace(hint, std::forward<decltype(k)>(k), std::forward<M>(obj))

for the last two overloads.

Returns: In the first two overloads, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace for the first two overloads and the same as emplace_hint for the last two overloads.

template<class K, class M>
pair<iterator, bool> insert_or_assign(K&& k, M&& obj);

template<class K, class M>
iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);

Constraints:

(28.1) The qualified-id Compare::is_transparent is valid and denotes a type.

(28.2) is_constructible_v<key_type, K> is true.

(28.3) is_assignable_v<mapped_type&, M> is true.

(28.4) is_constructible_v<mapped_type, M> is true.

Preconditions: The conversion from k into key_type constructs an object u, for which find(k) == find(u) is true.

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise, equivalent to

try_emplace(std::forward<K>(k), std::forward<M>(obj))

for the first overload or

try_emplace(hint, std::forward<K>(k), std::forward<M>(obj))

for the second overload.

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

void swap(flat_map& y) noexcept;

Effects: Equivalent to:

ranges::swap(compare, y.compare);
ranges::swap(c.keys, y.c.keys);
ranges::swap(c.values, y.c.values);

containers extract() &&;

Postconditions: *this is emptied, even if the function exits via an exception.

Returns: std::move(c).

§ 24.6.9.6
void replace(key_container_type&& key_cont, mapped_container_type&& mapped_cont);

36 **Preconditions:** \( key\_cont\).size() == \( mapped\_cont\).size() \) is true, the elements of \( key\_cont \) are sorted with respect to \( compare \), and \( key\_cont \) contains no equal elements.

37 **Effects:** Equivalent to:

\[
\begin{align*}
c.\text{keys} &= \text{std}::\text{move}(key\_cont); \\
c.\text{values} &= \text{std}::\text{move}(\text{mapped}\_\text{cont});
\end{align*}
\]

24.6.9.7 Erasure

```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer, class Predicate>
typename flat_map<Key, T, Compare, KeyContainer, MappedContainer>::size_type
erase_if(flat_map<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);
```

1 **Preconditions:** \( Key \) and \( T \) meet the \texttt{Cpp17MoveAssignable} requirements.

2 **Effects:** Let \( E \) be \( \text{bool}(\text{pred}(\text{pair<const Key&, const T&>(e)))) \). Erases all elements \( e \) in \( c \) for which \( E \) holds.

3 **Returns:** The number of elements erased.

4 **Complexity:** Exactly \( c.\text{size()} \) applications of the predicate.

5 **Remarks:** Stable (16.4.6.8). If an invocation of \texttt{erase_if} exits via an exception, \( c \) is in a valid but unspecified state (3.64).

\[\text{[Note 1: } c \text{ still meets its invariants, but can be empty.} \]

24.6.10 Class template flat_multimap

24.6.10.1 Overview

A \texttt{flat multimap} is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type \( T \) based on the keys. \texttt{flat multimap} supports iterators that meet the \texttt{Cpp17InputIterator} requirements and model the \texttt{random access iterator} concept (25.3.4.13).

2 A \texttt{flat multimap} meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). \texttt{flat multimap} meets the requirements of an associative container (24.2.7), except that:

(2.1) it does not meet the requirements related to node handles (24.2.5),

(2.2) it does not meet the requirements related to iterator invalidation, and

(2.3) the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

\[\text{[Note 1: A flat multimap does not meet the additional requirements of an allocator-aware container (24.2.2.5).} \]

3 A \texttt{flat multimap} also provides most operations described in 24.2.7 for equal keys. This means that a \texttt{flat multimap} supports the \texttt{a_eq} operations in 24.2.7 but not the \texttt{a_uniq} operations. For a \texttt{flat multimap<Key, T>} the \texttt{key_type} is \texttt{Key} and the \texttt{value_type} is \texttt{pair<Key, T>}.

4 Except as otherwise noted, operations on \texttt{flat multimap} are equivalent to those of \texttt{flat map}, except that \texttt{flat multimap} operations do not remove or replace elements with equal keys.

\[\text{[Example 1: flat multimap constructors and emplace do not erase non-unique elements after sorting them.} \]

5 A \texttt{flat multimap} maintains the following invariants:

(5.1) it contains the same number of keys and values;

(5.2) the keys are sorted with respect to the comparison object; and

(5.3) the value at offset \texttt{off} within the value container is the value associated with the key at offset \texttt{off} within the key container.

6 If any member function in 24.6.10.2 exits via an exception, the invariants are restored.

\[\text{[Note 2: This can result in the flat multimap being emptied.} \]

§ 24.6.10.1 1032
Any type \( C \) that meets the sequence container requirements (24.2.4) can be used to instantiate \( \text{flat\_multimap} \), as long as \( C::\text{iterator} \) meets the \( \text{Cpp17RandomAccessIterator} \) requirements and invocations of member functions \( C::\text{size} \) and \( C::\text{max\_size} \) do not exit via an exception. In particular, \text{vector} (24.3.11) and \text{deque} (24.3.8) can be used.

[Note 3: \text{vector<bool>} is not a sequence container. — end note]

The program is ill-formed if \( \text{Key} \) is not the same type as \( \text{KeyContainer::value\_type} \) or \( T \) is not the same type as \( \text{MappedContainer::value\_type} \).

The effect of calling a constructor that takes both \( \text{key\_container\_type} \) and \( \text{mapped\_container\_type} \) arguments with containers of different sizes is undefined.

The effect of calling a constructor or member function that takes a \( \text{sorted\_equivalent\_t} \) argument with a container, containers, or range that are not sorted with respect to \( \text{key\_comp()} \) is undefined.

§ 24.6.10.2 1037
```
template<class Key, class T, class Compare, class KeyContainer, class MappedContainer, class Allocator>
struct uses_allocator<flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>,
Allocator> :
bool_constant<uses_allocator_v<KeyContainer, Allocator> &&
uses_allocator_v<MappedContainer, Allocator>> { };
template<class Allocator>
    explicit flat_multimap(const Allocator& a);

template<class InputIterator, class Allocator>
    flat_multimap(InputIterator first, InputIterator last, const key_compare& comp,
                  const Allocator& a);

template<class InputIterator, class Allocator>
    flat_multimap(InputIterator first, InputIterator last, const Allocator& a);

template<container-compatible-range<value_type> R, class Allocator>
    flat_multimap(from_range_t, R&& rg, const Allocator& a);

template<container-compatible-range<value_type> R, class Allocator>
    flat_multimap(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
    flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                  const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
    flat_multimap(sorted_equivalent_t, InputIterator first, InputIterator last,
                  const Allocator& a);

template<class Allocator>
    flat_multimap(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);

template<class Allocator>
    flat_multimap(initializer_list<value_type> il, const Allocator& a);

template<class Allocator>
    flat_multimap(sorted_equivalent_t, initializer_list<value_type> il,
                  const key_compare& comp, const Allocator& a);

template<class Allocator>
    flat_multimap(sorted_equivalent_t, initializer_list<value_type> il, const Allocator& a);

Constraints: uses_allocator_v:key_container_type, Allocator> is true and uses_allocator_-
  v:mapped_container_type, Allocator> is true.

Effects: Equivalent to the corresponding non-allocator constructors except that c.keys and c.values
  are constructed with uses-allocator construction (20.2.8.2).

24.6.10.4 Erasure [flat.multimap.erosure]

template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
         class Predicate>
    typename flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>::size_type
    erase_if(flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);

Preconditions: Key and T meet the Cpp17MoveAssignable requirements.

Effects: Let E be bool(pred(pair<const Key&, const T&>(e))). Erases all elements e in c for
  which E holds.

Returns: The number of elements erased.

Complexity: Exactly c.size() applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but
  unspecified state (3.64).

[Note 1: c still meets its invariants, but can be empty. — end note]

24.6.11 Class template flat_set [flat.set]

24.6.11.1 Overview [flat.set.overview]

A flat_set is a container adaptor that provides an associative container interface that supports unique keys
(i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. flat_set
supports iterators that model the random_access_iterator concept (25.3.4.13).

A flat_set meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3),
plus the optional container requirements (24.2.2.4). flat_set meets the requirements of an associative
container (24.2.7), except that:

1. it does not meet the requirements related to node handles (24.2.5.1),
2. it does not meet the requirements related to iterator invalidation, and
the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_set does not meet the additional requirements of an allocator-aware container, as described in 24.2.2.5. — end note]

A flat_set also provides most operations described in 24.2.7 for unique keys. This means that a flat_set supports the a_uniq operations in 24.2.7 but not the a_eq operations. For a flat_set<Key>, both the key_type and value_type are Key.

Descriptions are provided here only for operations on flat_set that are not described in one of those sets of requirements or for operations where there is additional semantic information.

A flat_set maintains the invariant that the keys are sorted with respect to the comparison object.

If any member function in 24.6.11.2 exits via an exception, the invariant is restored.

Any sequence container (24.2.4) supporting Cpp17RandomAccessIterator can be used to instantiate flat_set. In particular, vector (24.3.11) and deque (24.3.8) can be used.

The program is ill-formed if Key is not the same type as KeyContainer::value_type.

The effect of calling a constructor or member function that takes a sorted_unique_t argument with a range that is not sorted with respect to key_comp(), or that contains equal elements, is undefined.

24.6.11.2 Definition

  flat_set(from_range_t, R&& rg, const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
  flat_set(sorted_unique_t, InputIterator first, InputIterator last,
            const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
  flat_set(sorted_unique_t, InputIterator first, InputIterator last, const Allocator& a);

template<class Allocator>
  flat_set(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);

template<class Allocator>
  flat_set(initializer_list<value_type> il, const Allocator& a);

template<class Allocator>
  flat_set(sorted_unique_t, initializer_list<value_type> il,
            const key_compare& comp, const Allocator& a);

template<class Allocator>
  flat_set(sorted_unique_t, initializer_list<value_type> il, const Allocator& a);

Constraints: uses_allocator_v<container_type, Allocator> is true.

Effects: Equivalent to the corresponding non-allocator constructors except that c is constructed with uses-allocator construction (20.2.8.2).

24.6.11.4 Modifiers

[flat.set.modifiers]

```
template<class K> pair<iterator, bool> insert(K&& x);
```

```
template<class K> iterator insert(const_iterator hint, K&& x);
```

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type. is_constructible_v<value_type, K> is true.

Preconditions: The conversion from x into value_type constructs an object u, for which find(x) == find(u) is true.

Effects: If the set already contains an element equivalent to x, *this and x are unchanged. Otherwise, inserts a new element as if byemplace(std::forward<K>(x)).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the element whose key is equivalent to x.

```
template<class InputIterator>
  void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to c as if by:
```c
  c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to compare; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

Complexity: \( N + M \log M \), where \( N \) is size() before the operation and \( M \) is distance(first, last).

Remarks: Since this operation performs an in-place merge, it may allocate memory.
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);

Effects: Equivalent to insert(first, last).
Complexity: Linear.

template<container-compatible-range<value_type> R>
void insert_range(R&& rg);

Effects: Adds elements to c as if by:
for (const auto& e : rg) {
    c.insert(c.end(), e);
}
Then, sorts the range of newly inserted elements with respect to compare; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.
Complexity: $N + M \log M$, where $N$ is size() before the operation and $M$ is ranges::distance(rg).
Remarks: Since this operation performs an in-place merge, it may allocate memory.

void swap(flat_set& y) noexcept;

Effects: Equivalent to:
ranges::swap(compare, y.compare);
ranges::swap(c, y.c);

container_type extract() &&;

Postconditions: *this is emptied, even if the function exits via an exception.
Returns: std::move(c).

void replace(container_type&& cont);

Preconditions: The elements of cont are sorted with respect to compare, and cont contains no equal elements.
Effects: Equivalent to: c = std::move(cont);

24.6.11.5 Erasure

template<class Key, class Compare, class KeyContainer, class Predicate>
typename flat_set<Key, Compare, KeyContainer>::size_type
erase_if(flat_set<Key, Compare, KeyContainer>& c, Predicate pred);

Preconditions: Key meets the Cpp17MoveAssignable requirements.
Effects: Let $E$ be bool(pred(as_const(e))). Erases all elements e in c for which $E$ holds.
Returns: The number of elements erased.
Complexity: Exactly c.size() applications of the predicate.
Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but unspecified state (3.64).
[Note 1: c still meets its invariants, but can be empty. — end note]

24.6.12 Class template flat_multiset

24.6.12.1 Overview

A flat_multiset is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of the keys themselves. flat_multiset supports iterators that model the random_access_iterator concept (25.3.4.13).

A flat_multiset meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). flat_multiset meets the requirements of an associative container (24.2.7), except that:
— it does not meet the requirements related to node handles (24.2.5.1),
— it does not meet the requirements related to iterator invalidation, and
— the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_multiset does not meet the additional requirements of an allocator-aware container, as described in 24.2.2.5. — end note]

3 A flat_multiset also provides most operations described in 24.2.7 for equal keys. This means that a flat_multiset supports the a_eq operations in 24.2.7 but not the a_uniq operations. For a flat_multiset<Key>, both the key_type and value_type are Key.

4 Descriptions are provided here only for operations on flat_multiset that are not described in one of the general sections or for operations where there is additional semantic information.

5 A flat_multiset maintains the invariant that the keys are sorted with respect to the comparison object.

6 If any member function in 24.6.12.2 exits via an exception, the invariant is restored.

[Note 2: This can result in the flat_multiset’s being emptied. — end note]

7 Any sequence container (24.2.4) supporting Cpp17RandomAccessIterator can be used to instantiate flat_multiset. In particular, vector (24.3.11) and deque (24.3.8) can be used.

[Note 3: vector<bool> is not a sequence container. — end note]

8 The program is ill-formed if Key is not the same type as KeyContainer::value_type.

9 The effect of calling a constructor or member function that takes a sorted_equivalent_t argument with a range that is not sorted with respect to key_comp() is undefined.

### 24.6.12.2 Definition

```cpp
namespace std {
    template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
    class flat_multiset {
    public:
        // types
        using key_type = Key;
        using value_type = Key;
        using key_compare = Compare;
        using value_compare = Compare;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = typename KeyContainer::size_type;
        using difference_type = typename KeyContainer::difference_type;
        using iterator = implementation-defined; // see 24.2
        using const_iterator = implementation-defined; // see 24.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;
        using container_type = KeyContainer;

        // 24.6.12.3, constructors
        flat_multiset() : flat_multiset(key_compare()) {} 

        template<class Allocator>
        flat_multiset(const flat_multiset&, const Allocator& a);
        template<class Allocator>
        flat_multiset(flat_multiset&&, const Allocator& a);

        explicit flat_multiset(container_type cont, const key_compare& comp = key_compare());
        template<class Allocator>
        flat_multiset(const container_type& cont, const Allocator& a);

9 Constraints: uses_allocator_v<container_type, Allocator> is true.
10 Effects: Equivalent to the corresponding non-allocator constructors except that c is constructed with
uses-allocator construction (20.2.8.2).

§ 24.6.12.4 Modifiers

[flat.multiset.modifiers]

template<class... Args> iterator emplace(Args&&... args);
1 Constraints: is_constructible_v<value_type, Args...> is true.
2 Effects: First, initializes an object t of type value_type with std::forward<Args>(args)..., then
inserts t as if by:
   auto it = ranges::upper_bound(c, t, compare);
   c.insert(it, std::move(t));
3 Returns: An iterator that points to the inserted element.

template<class InputIterator>
  void insert(InputIterator first, InputIterator last);
4 Effects: Adds elements to c as if by:
   c.insert(c.end(), first, last);
Then, sorts the range of newly inserted elements with respect to compare, and merges the resulting
sorted range and the sorted range of pre-existing elements into a single sorted range.
5 Complexity: \( N + M \log M \), where \( N \) is size() before the operation and \( M \) is distance(first, last).
6 Remarks: Since this operation performs an in-place merge, it may allocate memory.

template<class InputIterator>
  void insert(sorted_equivalent_t, InputIterator first, InputIterator last);
7 Effects: Equivalent to insert(first, last).
8  Complexity: Linear.

9  void swap(flat_multiset& y) noexcept;

9  Effects: Equivalent to:
  ranges::swap(compare, y.compare);
  ranges::swap(c, y.c);

10 container_type extract() &&;

10  Postconditions: *this is emptied, even if the function exits via an exception.

11 Returns: std::move(c).

12 void replace(container_type&& cont);

12  Preconditions: The elements of cont are sorted with respect to compare.

12  Effects: Equivalent to: c = std::move(cont);

24.6.12.5 Erasure [flat.multiset.erasuere]

template<class Key, class Compare, class KeyContainer, class Predicate>
typename flat_multiset<Key, Compare, KeyContainer>::size_type
erase_if(flat_multiset<Key, Compare, KeyContainer>& c, Predicate pred);

1  Preconditions: Key meets the Cpp17MoveAssignable requirements.

2  Effects: Let E be bool(pred(as_const(e))). Erases all elements e in c for which E holds.

3  Returns: The number of elements erased.

4  Complexity: Exactly c.size() applications of the predicate.

5  Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but
unspecified state (3.64).

[Note 1: c still meets its invariants, but can be empty. —end note]

24.6.13 Container adaptors formatting [container.adaptors.format]

For each of queue, priority_queue, and stack, the library provides the following formatter specialization
where adaptor-type is the name of the template:

namespace std {
  template<class charT, class T, formattable<charT> Container, class... U>
  struct formatter<adaptor-type<T, Container, U...>, charT> {

    private:
    using maybe-const-container = // exposition only
      fmt-maybe-const<Container, charT>;
    using maybe-const-adaptor = // exposition only
      maybe-const<is_const_v<maybe-const-container>, // see 26.2
        adaptor-type<T, Container, U...>>;
    formatter<ranges::ref_view<maybe-const-container>, charT> underlying_; // exposition only

    public:
    template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

    template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-adaptor& r, FormatContext& ctx) const;
  }
}

// 24.6.13 1053
template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-adaptor& r, FormatContext& ctx) const;

Effects: Equivalent to: return underlying_.format(r.c, ctx);

24.7 Views

24.7.1 General

The header <span> defines the view span. The header <mdspan> defines the class template mdspan and other facilities for interacting with these multidimensional views.

24.7.2 Contiguous access

24.7.2.1 Header <span> synopsis

#include <initializer_list>  // see 17.10.2

namespace std {
    // constants
    inline constexpr size_t dynamic_extent = numeric_limits<size_t>::max();

    // 24.7.2.2, class template span
    template<class ElementType, size_t Extent = dynamic_extent>
        class span;

    template<class ElementType, size_t Extent>
        constexpr bool ranges::enable_view<span<ElementType, Extent>> = true;

    template<class ElementType, size_t Extent>
        constexpr bool ranges::enable_borrowed_range<span<ElementType, Extent>> = true;

    // 24.7.2.3, views of object representation
    template<class ElementType, size_t Extent>
        span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
            as_bytes(span<ElementType, Extent> s) noexcept;

    template<class ElementType, size_t Extent>
        span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
            as_writable_bytes(span<ElementType, Extent> s) noexcept;
}

24.7.2.2 Class template span

24.7.2.2.1 Overview

A span is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

All member functions of span have constant time complexity.

namespace std {
    template<class ElementType, size_t Extent = dynamic_extent>
        class span {
            // constants and types
            using element_type = ElementType;
            using value_type = remove_cv_t<ElementType>;
            using size_type = size_t;
            using difference_type = ptrdiff_t;
            using pointer = element_type*;
            using const_pointer = const element_type*;
            using reference = element_type&;
            using const_reference = const element_type&;
            using iterator = implementation-defined;  // see 24.7.2.2.7
            using const_iterator = std::const_iterator<iterator>;
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::const_iterator<reverse_iterator>;
            static constexpr size_type extent = Extent;

§ 24.7.2.2.1

constexpr span<element_type, dynamic_extent> last(size_type count) const;

constexpr span<element_type, dynamic_extent> subspan(
  size_type offset, size_type count = dynamic_extent) const;

// 24.7.2.2.5, observers
constexpr size_type size() const noexcept;

constexpr size_type size_bytes() const noexcept;

[[nodiscard]] constexpr bool empty() const noexcept;

// 24.7.2.2.6, element access
constexpr reference operator[](size_type idx) const;  // freestanding-deleted
constexpr reference at(size_type idx) const;

constexpr reference front() const;

constexpr reference back() const;

constexpr pointer data() const noexcept;

// 24.7.2.2.7, iterator support
constexpr iterator begin() const noexcept;

constexpr iterator end() const noexcept;

constexpr const_iterator cbegin() const noexcept { return begin(); }

constexpr const_iterator cend() const noexcept { return end(); }

constexpr reverse_iterator rbegin() const noexcept;

constexpr reverse_iterator rend() const noexcept;

constexpr const_reverse_iterator crbegin() const noexcept { return rbegin(); }

constexpr const_reverse_iterator crend() const noexcept { return rend(); }

private:
  pointer data_;  // exposition only

  size_type size_;  // exposition only
};
template<class T, size_t N>
    span(T (&)[N]) -> span<T, N>;

template<class T, size_t N>
    span(array<T, N>&) -> span<T, N>;

template<class T, size_t N>
    span(const array<T, N>&) -> span<const T, N>;

template<class R>
    span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>;
template<
    size_t N>
constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;

template<class T, size_t N> constexpr span(array<T, N>& arr) noexcept;

template<class T, size_t N> constexpr span(const array<T, N>& arr) noexcept;

Constraints: Let U be remove_pointer_t<std::decltype(arr)>::data(arr)).

- extent == dynamic_extent || N == extent is true, and
- is_convertible_v<U(*)[], element_type(*)[]> is true.

[Note 3: The intent is to allow only qualification conversions of the array element type to element_type. — end note]

Effects: Constructs a span that is a view over the supplied array.

[Note 4: type_identity_t affects class template argument deduction. — end note]

Effects: Initializes data_ with ranges::data(r) and size_ with ranges::size(r).

Preconditions: If extent is not equal to dynamic_extent, then ranges::size(r) is equal to extent.

- R satisfies ranges::contiguous_range and ranges::sized_range.
- Either R satisfies ranges::borrowed_range or is_const_v<element_type> is true.
- remove_cvref_t<R> is not a specialization of span.
- remove_cvref_t<R> is not a specialization of array.
- is_array_v<remove_cvref_t<R>> is false.
- is_convertible_v<U(*)[], element_type(*)[]> is true.

[Note 5: The intent is to allow only qualification conversions of the range reference type to element_type. — end note]

Preconditions: If extent is not equal to dynamic_extent, then il.size() is equal to extent.

Constraints: is_const_v<element_type> is true.

Effects: Initializes data_ with il.begin() and size_ with il.size().

Postconditions: other.size() == size() & other.data() == data().

Remarks: The expression inside explicit is equivalent to:
extent != dynamic_extent && OtherExtent == dynamic_extent

constexpr span& operator=(const span& other) noexcept = default;

27

**Postconditions**: size() == other.size() && data() == other.data().

### 24.7.2.2.3 Deduction guides

**template<class It, class EndOrSize>**

span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;

**Constraints**: It satisfies contiguous_iterator.

**template<class R>**

span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;

**Constraints**: R satisfies ranges::contiguous_range.

### 24.7.2.2.4 Subviews

**template<size_t Count> constexpr span<element_type, Count> first() const;**

**Mandates**: Count <= Extent is true.

**Preconditions**: Count <= size() is true.

**Effects**: Equivalent to: return R{data(), Count}; where R is the return type.

**template<size_t Count> constexpr span<element_type, Count> last() const;**

**Mandates**: Count <= Extent is true.

**Preconditions**: Count <= size() is true.

**Effects**: Equivalent to: return R{data() + (size() - Count), Count}; where R is the return type.

**template<size_t Offset, size_t Count = dynamic_extent>**

constexpr span<element_type, see below> subspan() const;

**Mandates**: Offset <= Extent && (Count == dynamic_extent || Count <= Extent - Offset) is true.

**Preconditions**: Offset <= size() && (Count == dynamic_extent || Count <= size() - Offset) is true.

**Effects**: Equivalent to:

```
return span<ElementType, see below>(
    data() + Offset, Count != dynamic_extent ? Count : size() - Offset);
```

**Remarks**: The second template argument of the returned span type is:

```
Count != dynamic_extent ? Count :
    (Extent != dynamic_extent ? Extent - Offset :
     dynamic_extent)
```

**constexpr span<element_type, dynamic_extent> first(size_type count) const;**

**Preconditions**: count <= size() is true.

**Effects**: Equivalent to: return {data(), count};

**constexpr span<element_type, dynamic_extent> last(size_type count) const;**

**Preconditions**: count <= size() is true.

**Effects**: Equivalent to: return {data() + (size() - count), count};

**constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;**

**Preconditions**: offset <= size() && (count == dynamic_extent || count <= size() - offset)
is true.

Effects: Equivalent to:

```
return {data() + offset, count == dynamic_extent ? size() - offset : count};
```

### 24.7.2.2.5 Observers

```cpp
constexpr size_type size() const noexcept;
```

Effects: Equivalent to:

```
return size_
```

### 24.7.2.2.6 Element access

```cpp
constexpr reference operator[](size_type idx) const;
```

Preconditions: idx < size() is true.

Effects: Equivalent to:

```
return *(data() + idx);
```

### 24.7.2.2.7 Iterator support

```cpp
using iterator = implementation-defined;
```

The type models contiguous_iterator (25.3.4.14), meets the Cpp17RandomAccessIterator requirements (25.3.5.7), and meets the requirements for constexpr iterators (25.3.1), whose value type is value_type and whose reference type is reference.

All requirements on container iterators (24.2.2.2) apply to span::iterator as well.
24.7.2.3 Views of object representation

```cpp
template<class ElementType, size_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;
```

**Effects:** Equivalent to:
```
return R{reinterpret_cast<const byte*>(s.data()), s.size_bytes()};
```
where `R` is the return type.

```cpp
template<class ElementType, size_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;
```

**Constraints:** `is_const_v<ElementType>` is `false`.

**Effects:** Equivalent to:
```
return R{reinterpret_cast<byte*>(s.data()), s.size_bytes()};
```
where `R` is the return type.

24.7.3 Multidimensional access

### 24.7.3.1 Overview

A **multidimensional index space** is a Cartesian product of integer intervals. Each interval can be represented by a half-open range `[L_i, U_i)`, where `L_i` and `U_i` are the lower and upper bounds of the `i`th dimension. The **rank** of a multidimensional index space is the number of intervals it represents. The **size** of a multidimensional index space is the product of `U_i - L_i` for each dimension `i` if its rank is greater than 0, and 1 otherwise.

An integer `r` is a **rank index** of an index space `S` if `r` is in the range `[0, rank of `S`)).

A pack of integers `idx` is a **multidimensional index** in a multidimensional index space `S` (or representation thereof) if both of the following are true:

1. `sizeof...(idx)` is equal to the rank of `S`, and
2. for every rank index `i` of `S`, the `i`th value of `idx` is an integer in the interval `[L_i, U_i)` of `S`.

### 24.7.3.2 Header `<mdspan>` synopsis

```cpp
// all freestanding
namespace std {
  // 24.7.3.3, class template extents
  template<class IndexType, size_t... Extents>

    convertible_to<tuple_element_t<1, T>, IndexType>;

24.7.3.3 Class template extents [mdspan.extents]

24.7.3.3.1 Overview [mdspan.extents.overview]
The class template extents represents a multidimensional index space of rank equal to sizeof...(Extents).
In subclause (24.7), extents is used synonymously with multidimensional index space.

namespace std {
    template<class IndexType, size_t... Extents>
    class extents {
        public:
            using index_type = IndexType;
            using size_type = make_unsigned_t<index_type>;
            using rank_type = size_t;

            // 24.7.3.3.4, observers of the multidimensional index space
            static constexpr rank_type rank() noexcept { return sizeof...(Extents); }
            static constexpr rank_type rank_dynamic() noexcept { return dynamic_index(rank()); }
            static constexpr size_t static_extent(rank_type) noexcept;
            constexpr index_type extent(rank_type) const noexcept;

            // 24.7.3.3.3, constructors
            constexpr extents() noexcept = default;

            template<class OtherIndexType, size_t... OtherExtents>
            constexpr explicit(see below) extents(const extents<OtherIndexType, OtherExtents...>&) noexcept;
            template<class... OtherIndexTypes>
            constexpr explicit extents(OtherIndexTypes...) noexcept;
            template<class OtherIndexType, size_t N>
            constexpr explicit(N != rank_dynamic())
                extents(span<OtherIndexType, N>) noexcept;
            template<class OtherIndexType, size_t N>
            constexpr explicit(N != rank_dynamic())
                extents(const array<OtherIndexType, N>&) noexcept;

    };

§ 24.7.3.3.1
template<class OtherIndexType, size_t... OtherExtents>
friend constexpr bool operator==(const extents&,
    const extents<OtherIndexType, OtherExtents...>&) noexcept;

// 24.7.3.3.2, exposition-only helpers
constexpr size_t
fwd-prod-of-extents(rank_type) const noexcept; // exposition only
constexpr size_t
rev-prod-of-extents(rank_type) const noexcept; // exposition only

template<class OtherIndexType>
static constexpr auto
index-cast(OtherIndexType&&) noexcept; // exposition only

private:
static constexpr rank_type
dynamic-index(rank_type) noexcept; // exposition only
static constexpr rank_type
dynamic-index-inv(rank_type) noexcept; // exposition only
array<index_type, rank_dynamic()> dynamic-extents{}; // exposition only

};

template<class... Integrals>
explicit extents(Integrals...)
    -> see below;

Mandates:
(1.1) — IndexType is a signed or unsigned integer type, and
(1.2) — each element of Extents is either equal to dynamic_extent, or is representable as a value of type
IndexType.

Each specialization of extents models regular and is trivially copyable.

Let $E_r$ be the $r^{th}$ element of Extents. $E_r$ is a dynamic extent if it is equal to dynamic_extent, otherwise $E_r$
is a static extent. Let $D_r$ be the value of dynamic-extents[dynamic-index(r)] if $E_r$ is a dynamic extent, otherwise $E_r$.

The $r^{th}$ interval of the multidimensional index space represented by an extents object is $[0, D_r)$.

24.7.3.3.2 Exposition-only helpers

static constexpr rank_type
dynamic-index(rank_type i) noexcept;

1 Preconditions: $i \leq \text{rank()}$ is true.
2 Returns: The number of $E_r$ with $r < i$ for which $E_r$ is a dynamic extent.

static constexpr rank_type
dynamic-index-inv(rank_type i) noexcept;

3 Preconditions: $i < \text{rank_dynamic()}$ is true.
4 Returns: The minimum value of $r$ such that dynamic-index$(r + 1) == i + 1$ is true.

constexpr size_t
fwd-prod-of-extents(rank_type i) const noexcept;

5 Preconditions: $i \leq \text{rank()}$ is true.
6 Returns: If $i > 0$ is true, the product of $\text{extent}(k)$ for all $k$ in the range $[0, i)$, otherwise 1.

constexpr size_t
rev-prod-of-extents(rank_type i) const noexcept;

7 Preconditions: $i < \text{rank()}$ is true.
8 Returns: If $i + 1 < \text{rank()}$ is true, the product of $\text{extent}(k)$ for all $k$ in the range $[i + 1, \text{rank()}$), otherwise 1.

Effects:
(9.1) — If OtherIndexType is an integral type other than bool, then equivalent to return $i$;
(9.2) — otherwise, equivalent to return static_cast<index_type>(i);.
[Note 1: This function will always return an integral type other than bool. Since this function’s call sites are constrained on convertibility of OtherIndexType to index_type, integer-class types can use the static_cast branch without loss of precision. — end note]

24.7.3.3.3 Constructors

```cpp
template<class OtherIndexType, size_t... OtherExtents>
constexpr explicit(see below)
    extents(const extents<OtherIndexType, OtherExtents...>& other) noexcept;
```

1 Constraints:
(1.1) sizeof...(OtherExtents) == rank() is true.
(1.2) ((OtherExtents == dynamic_extent || Extents == dynamic_extent || OtherExtents == Extents) && ...) is true.

2 Preconditions:
(2.1) other.extent(r) equals E_r for each r for which E_r is a static extent, and
(2.2) either
    (2.2.1) sizeof...(OtherExtents) is zero, or
    (2.2.2) other.extent(r) is representable as a value of type index_type for every rank index r of other.

3 Postconditions: *this == other is true.

4 Remarks: The expression inside explicit is equivalent to:

```cpp
((Extents != dynamic_extent) && (OtherExtents == dynamic_extent)) || ...
|| (numeric_limits<index_type>::max() < numeric_limits<OtherIndexType>::max())
```

```cpp
template<class... OtherIndexTypes>
constexpr explicit extents(OtherIndexTypes... exts) noexcept;
```

5 Let N be sizeof...(OtherIndexTypes), and let exts_arr be array<index_type, N>{static_cast<
    index_type>(std::move(exts))...}.

6 Constraints:
(6.1) (is_convertible_v<OtherIndexTypes, index_type> && ...) is true,
(6.2) (is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...) is true, and
(6.3) N == rank_dynamic() || N == rank() is true.

[Note 1: One can construct extents from just dynamic extents, which are all the values getting stored, or from all the extents with a precondition. — end note]

7 Preconditions:
(7.1) If N != rank_dynamic() is true, exts_arr[r] equals E_r for each r for which E_r is a static extent, and
(7.2) either
    (7.2.1) sizeof...(exts) == 0 is true, or
    (7.2.2) each element of exts is representable as a nonnegative value of type index_type.

8 Postconditions: *this == extents(exts_arr) is true.

```cpp
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic())
    extents(span<OtherIndexType, N> exts) noexcept;
```

9 Constraints:
(9.1) is_convertible_v<const OtherIndexType&, index_type> is true,
(9.2) is_nothrow_constructible_v<index_type, const OtherIndexType&> is true, and
(9.3) N == rank_dynamic() || N == rank() is true.
Preconditions:

(10.1) If N != rank_dynamic() is true, exts[r] equals Er for each r for which Er is a static extent, and
(10.2) either
(10.2.1) N is zero, or
(10.2.2) exts[r] is representable as a nonnegative value of type index_type for every rank index r.

Effects:

(11.1) If N equals dynamic_rank(), for all d in the range [0, rank_dynamic()), direct-non-list-initializes dynamic-extents[d] with as_const(exts[d]).
(11.2) Otherwise, for all d in the range [0, rank_dynamic()), direct-non-list-initializes dynamic-ex
tents[d] with as_const(exts[dynamic-index-inv(d)]).

template<class... Integrals>
explicit extents(Integrals...) -> see below;

Constraints: (is_convertible_v<Integrals, size_t> && ...) is true.
Remarks: The deduced type is dextents<size_t, sizeof...(Integrals)>.

24.7.3.3.4 Observers of the multidimensional index space

static constexpr size_t static_extent(rank_type i) noexcept;
Preconditions: i < rank() is true.
Returns: Ei.

cconstexpr index_type extent(rank_type i) const noexcept;
Preconditions: i < rank() is true.
Returns: Di.

24.7.3.3.5 Comparison operators

template<class OtherIndexType, size_t... OtherExtents>
friend constexpr bool operator==(const extents& lhs, const extents<OtherIndexType, OtherExtents...>& rhs) noexcept;
Returns: true if lhs.rank() equals rhs.rank() and if lhs.extent(r) equals rhs.extent(r) for every rank index r of rhs, otherwise false.

24.7.3.3.6 Alias template dextents

template<class IndexType, size_t Rank>
using dextents = extents<IndexType, Rank>;
Result: A type E that is a specialization of extents such that E::rank() == Rank && E::rank() == E::rank_dynamic() is true, and E::index_type denotes IndexType.

24.7.3.4 Layout mapping

24.7.3.4.1 General

In subclauses 24.7.3.4.2 and 24.7.3.4.3:
(1.1) M denotes a layout mapping class.
(1.2) m denotes a (possibly const) value of type M.
(1.3) i and j are packs of (possibly const) integers that are multidimensional indices in m.extents().
[Note 1: The type of each element of the packs can be a different integer type. — end note]
(1.4) r is a (possibly const) rank index of typename M::extent_type.
(1.5) d is a pack of (possibly const) integers for which sizeof...(d) == M::extent_type::rank() is true, the rth element is equal to 1, and all other elements are equal to 0.

In subclauses 24.7.3.4.2 through 24.7.3.4.7, let is-mapping-of be the exposition-only variable template defined as follows:
template<class Layout, class Mapping>
constexpr bool is-mapping-of = // exposition only
    is_same_v<typename Layout::template mapping<typename Mapping::extents_type>, Mapping>;

24.7.3.4.2 Requirements [mdspan.layout.reqmts]

A type \( M \) meets the layout mapping requirements if

1. \( M \) models copyable and equality_comparable,
2. \( \text{is-nothrow-move-constructible}_v(M) \) is true,
3. \( \text{is-nothrow-move-assignable}_v(M) \) is true,
4. \( \text{is-nothrow-swappable}_v(M) \) is true, and
5. the following types and expressions are well-formed and have the specified semantics.

**typename M::extents_type**

Result: A type that is a specialization of extents.

**typename M::index_type**

Result: typename M::extents_type::index_type.

**typename M::rank_type**

Result: typename M::extents_type::rank_type.

**typename M::layout_type**

Result: A type \( MP \) that meets the layout mapping policy requirements (24.7.3.4.3) and for which \( \text{is-mapping-of}(MP, M) \) is true.

\( m \).extents()

Result: const typename M::extents_type&

\( m(i...) \)

Result: typename M::index_type

Returns: A nonnegative integer less than numeric_limits<typename M::index_type>::max() and less than or equal to numeric_limits<

\( m(i...) == m(static\_cast<typename M::index\_type>(i)...) \)

Result: bool

Returns: true

\( m \).required_span_size()

Result: typename M::index_type

Returns: If the size of the multidimensional index space \( m \).extents() is 0, then 0, else 1 plus the maximum value of \( m(i...) \) for all \( i \).

\( m \).is_unique()

Result: bool

Returns: true only if for every \( i \) and \( j \) where \( (i != j || ...) \) is true, \( m(i...) != m(j...) \) is true.

[Note 1: A mapping can return false even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is unique. — end note]

\( m \).is_exhaustive()

Result: bool

Returns: true only if for all \( k \) in the range \( [0, m \).required_span_size() \) there exists an \( i \) such that \( m(i...) \) equals \( k \).

[Note 2: A mapping can return false even if the condition is met. For certain layouts, it is possibly not feasible to determine efficiently whether the layout is exhaustive. — end note]
m.is_strided()

Result: bool
Returns: true only if for every rank index r of m.extents() there exists an integer s_r such that, for all i where (i + d_r) is a multidimensional index in m.extents() \((24.7.3.1), m((i + d_r)\ldots) - m(i\ldots)\) equals s_r.

[Note 3: This implies that for a strided layout \(m(i_0,\ldots,i_k) = m(0,\ldots,0) + i_0 \times s_0 + \cdots + i_k \times s_k\). — end note]

m.stride(r)

Preconditions: m.is_strided() is true.
Result: typename M::index_type
Returns: s_r as defined in m.is_strided() above.

M::is_always_unique()

Result: A constant expression (7.7) of type bool.
Returns: true only if m.is_unique() is true for all possible objects m of type M.

[Note 5: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is unique. — end note]

M::is_always_exhaustive()

Result: A constant expression (7.7) of type bool.
Returns: true only if m.is_exhaustive() is true for all possible objects m of type M.

[Note 6: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is exhaustive. — end note]

M::is_always_strided()

Result: A constant expression (7.7) of type bool.
Returns: true only if m.is_strided() is true for all possible objects m of type M.

[Note 7: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is strided. — end note]

24.7.3.4.3 Layout mapping policy requirements [mdspan.layout.policy.reqmts]

A type MP meets the layout mapping policy requirements if for a type E that is a specialization of extents, MP::mapping<E> is valid and denotes a type X that meets the layout mapping requirements (24.7.3.4.2), and for which the qualified-id X::layout_type is valid and denotes the type MP and the qualified-id X::extents_type denotes E.

24.7.3.4.4 Layout mapping policies [mdspan.layout.policy.overview]

namespace std {
  struct layout_left {
    template<class Extents>
      class mapping;
  };
  struct layout_right {
    template<class Extents>
      class mapping;
  };
  struct layout_stride {
    template<class Extents>
      class mapping;
  };
}

1 Each of layout_left, layout_right, and layout_stride meets the layout mapping policy requirements and is a trivial type.
24.7.3.4.5 Class template `layout_left::mapping`  

24.7.3.4.5.1 Overview

`layout_left` provides a layout mapping where the leftmost extent has stride 1, and strides increase left-to-right as the product of extents.

```cpp
namespace std {
  template<class Extents>
  class layout_left::mapping {
    public:
      using extents_type = Extents;
      using index_type = typename extents_type::index_type;
      using size_type = typename extents_type::size_type;
      using rank_type = typename extents_type::rank_type;
      using layout_type = layout_left;

          SliceSpecifiers... slices) const -> see below;
      template<class... SliceSpecifiers>
        friend constexpr auto submdspan_mapping( // exposition only
          const mapping& src, SliceSpecifiers... slices) {
          return src.submdspan_mapping_impl(slices...);
        }
  }
}
```

§ 24.7.3.4.5
2 If Extents is not a specialization of extents, then the program is ill-formed.

3 layout_left::mapping<E> is a trivially copyable type that models regular for each E.

4 Mandates: If Extents::rank_dynamic() == 0 is true, then the size of the multidimensional index space Extents() is representable as a value of type typename Extents::index_type.

### 24.7.3.4.5.2 Constructors

```cpp
constexpr mapping(const extents_type& e) noexcept;
```

1 **Preconditions:** The size of the multidimensional index space e is representable as a value of type index_type (6.8.2).

2 **Effects:** Direct-non-list-initializes extents_ with e.

```cpp
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>) mapping(const mapping<OtherExtents>& other) noexcept;
```

3 **Constraints:** is_constructible_v<extents_type, OtherExtents> is true.

4 **Preconditions:** other.required_span_size() is representable as a value of type index_type (6.8.2).

5 **Effects:** Direct-non-list-initializes extents_ with other.extents().

```cpp
template<class OtherExtents>
constexpr explicit(extents_type::rank() > 0) mapping(const layout_stride::mapping<OtherExtents>& other);
```

6 **Constraints:** is_constructible_v<extents_type, OtherExtents> is true.

7 **Preconditions:**

8 **Effects:** Direct-non-list-initializes extents_ with other.extents().

### 24.7.3.4.5.3 Observers

```cpp
constexpr index_type required_span_size() const noexcept;
```

1 **Returns:** extents().fwd-prod-of-extents(extents_type::rank()).

```cpp
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

2 **Constraints:**

(2.1) sizeof...(Indices) == extents_type::rank() is true.

(2.2) (is_convertible_v<Indices, index_type> && ...) is true, and

(2.3) (is_nothrow_constructible_v<index_type, Indices> && ...) is true.
Preconditions: extents_type::index-cast(i) is a multidimensional index in extents_ (24.7.3.1).

Effects: Let P be a parameter pack such that

is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>

is true. Equivalent to:

return ((static_cast<index_type>(i) * stride(P)) + ... + 0);

constexpr index_type stride(rank_type i) const;

Constraints: extents_type::rank() > 0 is true.

Preconditions: i < extents_type::rank() is true.

Returns: extents().fwd-prod-of-extents(i).

24.7.3.4.6 Class template layout_right::mapping

24.7.3.4.6.1 Overview

layout_right provides a layout mapping where the rightmost extent is stride 1, and strides increase right-to-left as the product of extents.

namespace std {
    template<class Extents>
    class layout_right::mapping {
        public:
            using extents_type = Extents;
            using index_type = typename extents_type::index_type;
            using size_type = typename extents_type::size_type;
            using rank_type = typename extents_type::rank_type;
            using layout_type = layout_right;

            // 24.7.3.4.6.2, constructors
            constexpr mapping() noexcept = default;
            constexpr mapping(const mapping&) noexcept = default;
            constexpr mapping(const extents_type&) noexcept;
            template<class OtherExtents>
                constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
                mapping(const mapping<OtherExtents>&) noexcept;
            template<class OtherExtents>
                constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
                mapping(const layout_left::mapping<OtherExtents>&) noexcept;
            template<class OtherExtents>
                constexpr explicit(extents_type::rank() > 0)
                mapping(const layout_stride::mapping<OtherExtents>&) noexcept;

            constexpr mapping& operator=(const mapping&) noexcept = default;

            // 24.7.3.4.6.3, observers
            constexpr const extents_type& extents() const noexcept { return extents_; }
            constexpr index_type required_span_size() const noexcept;
            template<class... Indices>
                constexpr index_type operator()(Indices...) const noexcept;

            static constexpr bool is_always_unique() noexcept { return true; }
            static constexpr bool is_always_exhaustive() noexcept { return true; }
            static constexpr bool is_always_strided() noexcept { return true; }

§ 24.7.3.4.6
static constexpr bool is_unique() noexcept { return true; }
static constexpr bool is_exhaustive() noexcept { return true; }
static constexpr bool is_strided() noexcept { return true; }

constexpr index_type stride(rank_type) const noexcept;

friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

private:
  extents_type extents_; // exposition only

  // 24.7.3.7.6, submdspan mapping specialization
  template<class... SliceSpecifiers>
    constexpr auto submdspan_mapping-impl(
      SliceSpecifiers... slices) const -> see below;

  template<class... SliceSpecifiers>
    friend constexpr auto submdspan_mapping(
      const mapping& src, SliceSpecifiers... slices) {
    return src.submdspan_mapping-impl(slices...);
  }

2 If Extents is not a specialization of extents, then the program is ill-formed.

3 layout_right::mapping<E> is a trivially copyable type that models regular for each E.

4 Mandates: If Extents::rank_dynamic() == 0 is true, then the size of the multidimensional index space Extents() is representable as a value of type typename Extents::index_type.

24.7.3.4.6.2 Constructors

constexpr mapping(const extents_type& e) noexcept;

1 Preconditions: The size of the multidimensional index space e is representable as a value of type index_type (6.8.2).

2 Effects: Direct-non-list-initializes extents with e.

template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping& OtherExtents&) noexcept;

3 Constraints: is_convertible_v<extents_type, OtherExtents> is true.

4 Preconditions: OtherExtents::required_span_size() is representable as a value of type index_type (6.8.2).

5 Effects: Direct-non-list-initializes extents with other.extents().

template<class OtherExtents>
  constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_stride::mapping<OtherExtents>& other) noexcept;

6 Constraints:
7  — extents_type::rank() <= 1 is true, and
8  — is_convertible_v<extents_type, OtherExtents> is true.

7 Preconditions: other.required_span_size() is representable as a value of type index_type (6.8.2).

8 Effects: Direct-non-list-initializes extents with other.extents().

template<class OtherExtends>
  constexpr explicit(extents_type::rank() > 0)
    mapping(const layout_stride::mapping<OtherExtents>& other) noexcept;

9 Constraints: is_convertible_v<extents_type, OtherExtents> is true.

10 Preconditions:
If `extents_type::rank() > 0` is true, then for all `r` in the range `0, extents_type::rank()`, `other.stride(r)` equals `other.extents().rev-prod-of-extents(r)`.

- `other.required_span_size()` is representable as a value of type `index_type (6.8.2)`. **Effects:** Direct-non-list-initializes `extents_` with `other.extents()`.

### 24.7.3.4.6.3 Observers

- `required_span_size()` const noexcept;
  
  **Returns:** `extents().fwd-prod-of-extents(extents_type::rank())`.

```cpp
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

**Constraints:**

- `sizeof...(Indices) == extents_type::rank()` is true.
- `(is_convertible_v<Indices, index_type> && ...)` is true, and
- `(is_nothrow_constructible_v<index_type, Indices> && ...)` is true.

** Preconditions:**

- `extents_type::index-cast(i)` is a multidimensional index in `extents_` (24.7.3.1).

** Effects:** Let `P` be a parameter pack such that `is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>` is true. Equivalent to:

```
return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
```

```cpp
constexpr index_type stride(rank_type i) const noexcept;
```

**Constraints:**

- `extents_type::rank() > 0` is true.

** Preconditions:**

- `i < extents_type::rank()` is true.

**Returns:** `extents().rev-prod-of-extents(i)`.

```cpp
friend constexpr bool operator==(const mapping& x, const mapping<OtherExtents>& y) noexcept;
```

**Constraints:**

- `extents_type::rank() == OtherExtents::rank()` is true.

** Effects:** Equivalent to: `return x.extents() == y.extents();`

### 24.7.3.4.7 Class template `layout_stride::mapping`

#### 24.7.3.4.7.1 Overview

`layout_stride` provides a layout mapping where the strides are user-defined.

```cpp
namespace std {
    template<class Extents>
    class layout_stride::mapping {
    public:
        using extents_type = Extents;
        using index_type = typename extents_type::index_type;
        using size_type = typename extents_type::size_type;
        using rank_type = typename extents_type::rank_type;
        using layout_type = layout_stride;

    private:
        static constexpr rank_type rank_ = extents_type::rank(); // exposition only
    
    public:
        // 24.7.3.4.7.3, constructors
        constexpr mapping() noexcept;
        constexpr mapping(const mapping&) noexcept = default;
        template<class OtherIndexType>
        constexpr mapping(const extents_type&, span<OtherIndexType, rank_>) noexcept;
        template<class OtherIndexType>
        constexpr mapping(const extents_type&, const array<OtherIndexType, rank_> &) noexcept;
    };
template<
class StridedLayoutMapping>
constexpr explicit(see below) mapping(const StridedLayoutMapping&) noexcept;

constexpr mapping& operator=(const mapping&) noexcept = default;

// 24.7.3.4.7.4, observers
constexpr const extents_type& extents() const noexcept { return extents_; }
constexpr array<index_type, rank_> strides() const noexcept { return strides_; }

constexpr index_type required_span_size() const noexcept;

template<class... Indices>
constexpr index_type operator()(Indices...) const noexcept;

static constexpr bool is_always_unique() noexcept { return true; }
static constexpr bool is_always_exhaustive() noexcept { return false; }
static constexpr bool is_always_strided() noexcept { return true; }

static constexpr bool is_unique() noexcept { return true; }

constexpr bool is_exhaustive() const noexcept;

static constexpr bool is_strided() noexcept { return true; }

constexpr index_type stride(rank_type i) const noexcept { return strides_[i]; }

template<class OtherMapping>
friend constexpr bool operator==(const mapping&, const OtherMapping&) noexcept;

private:

extents_type extents_; // exposition only
array<index_type, rank_> strides_; // exposition only

// 24.7.3.7.6, submdspan mapping specialization

template<class... SliceSpecifiers>
constexpr auto submdspan-mapping-impl(
    SliceSpecifiers... slices) const -> see below;

friend constexpr auto submdspan_mapping(
    const mapping& src, SliceSpecifiers... slices) {
    return src.submdspan-mapping-impl(slices...);
}

}
Let \texttt{is-extents} be the exposition-only variable template defined as follows:

\texttt{template<class T> constexpr bool \texttt{is-extents} = false; // exposition only}

\texttt{template<class IndexType, size_t... Args> constexpr bool \texttt{is-extents}<\texttt{extents<IndexType, Args...>>} = true; // exposition only}

Let \texttt{layout-mapping-alike} be the exposition-only concept defined as follows:

\texttt{template<class M> concept layout-mapping-alike = requires {
  requires \texttt{is-extents<typename M::extents_type>};
  \{ M::is_always_strided() \} \rightarrow \text{same_as<bool>};
  \{ M::is_always_exhaustive() \} \rightarrow \text{same_as<bool>};
  \{ M::is_always_unique() \} \rightarrow \text{same_as<bool>};
  \text{bool_constant<M::is_always_strided>::value};
  \text{bool_constant<M::is_always_exhaustive>::value};
  \text{bool_constant<M::is_always_unique>::value};
};

[Note 1: This concept checks that the functions \texttt{M::is_always_strided}, \texttt{M::is_always_exhaustive}, \texttt{M::is_always_unique} exist, are constant expressions, and have a return type of \texttt{bool}. — end note]

\subsection*{24.7.3.4.7.3 Constructors [mdspan.layout.stride.cons]}

\texttt{constexpr mapping() noexcept;}

\textit{Preconditions:} \texttt{layout_right::mapping<extents_type>().required_span_size()} is representable as a value of type \texttt{index_type} (6.8.2).

\textit{Effects:} Direct-non-list-initializes \texttt{extents_} with \texttt{extents_type()}, and for all \texttt{d} in the range \([0, \text{rank}_-])

direct-non-list-initializes \texttt{strides_[d]} with \texttt{layout_right::mapping<extents_type>().stride(d)}.

\texttt{template<class OtherIndexType>
constexpr mapping(const extents_type& e, span<OtherIndexType, rank_> s) noexcept;
}

\texttt{template<class OtherIndexType>
constexpr mapping(const extents_type& e, const array<OtherIndexType, rank_> & s) noexcept;
}

\textit{Constraints:}

\begin{enumerate}
  \item \texttt{is_convertible_v<const OtherIndexType&, index_type> is true, and}
  \item \texttt{is_nothrow_constructible_v<index_type, const OtherIndexType&> is true.}
\end{enumerate}

\textit{Preconditions:}

\begin{enumerate}
  \item The result of converting \texttt{s[i]} to \texttt{index_type} is greater than 0 for all \texttt{i} in the range \([0, \text{rank}_-])
  \item \texttt{REQUIRED-SPAN-SIZE(e, s)} is representable as a value of type \texttt{index_type} (6.8.2).
  \item If \texttt{rank_-} is greater than 0, then there exists a permutation \(P\) of the integers in the range \([0, \text{rank}_-])
  such that \(s[p_i] \geq s[p_{i-1}] \ast e.extent(p_{i-1})\) is \texttt{true} for all \texttt{i} in the range \([1, \text{rank}_-])
  where \(p_i\) is the \texttt{i}th element of \(P\).
  \[Note 1: \text{For layout_stride, this condition is necessary and sufficient for \texttt{is_unique()} to be true. — end note}\]
\end{enumerate}

\textit{Effects:} Direct-non-list-initializes \texttt{extents_} with \texttt{e}, and for all \texttt{d} in the range \([0, \text{rank}_-])

direct-non-list-initializes \texttt{strides_[d]} with \texttt{as_const(s[d])}.

\texttt{template<class StridedLayoutMapping>
constexpr explicit(see below)
mapping(const StridedLayoutMapping& other) noexcept;
}

\textit{Constraints:}

\begin{enumerate}
  \item \texttt{layout-mapping-alike<StridedLayoutMapping> is satisfied.}
  \item \texttt{is_constructible_v<extents_type, typename StridedLayoutMapping::extents_type> is true.}
  \item \texttt{StridedLayoutMapping::is_always_unique()} is \texttt{true.}
\end{enumerate}
StridedLayoutMapping::is_always_strided() is true.

**Preconditions:**

1. StridedLayoutMapping meets the layout mapping requirements (24.7.3.4.2),
2. other.stride(r) > 0 is true for every rank index r of extents(),
3. other.required_span_size() is representable as a value of type index_type (6.8.2), and
4. OFFSET(other) == 0 is true.

**Effects:** Direct-non-list-initializes extents_ with other.extents(), and for all d in the range [0, rank_),
direct-non-list-initializes strides_[d] with other.stride(d).

**Remarks:** The expression inside explicit is equivalent to:

```cpp
!(is_convertible_v<typename StridedLayoutMapping::extents_type, extents_type> &&
 (is-mapping-of<layout_left, StridedLayoutMapping> ||
  is-mapping-of<layout_right, StridedLayoutMapping> ||
  is-mapping-of<layout_stride, StridedLayoutMapping>))
```

### 24.7.3.4.7.4 Observers

```cpp
constexpr index_type required_span_size() const noexcept;
```

**Returns:** REQUIRED-SPAN-SIZE(extents(), strides_).

```cpp
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

**Constraints:**

1. sizeof...(Indices) == rank_ is true,
2. (is_convertible_v<Indices, index_type> && ...) is true, and
3. (is_nothrow_constructible_v<index_type, Indices> && ...) is true.

**Preconditions:** extents_type::index-cast(i) is a multidimensional index in extents_ (24.7.3.1).

**Effects:** Let P be a parameter pack such that

```
is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>
```

is true. Equivalent to:

```
return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
```

```cpp
constexpr bool is_exhaustive() const noexcept;
```

**Returns:**

1. true if rank_ is 0.
2. Otherwise, true if there is a permutation P of the integers in the range [0, rank_) such that
   `stride(p_i) == 1, and stride(p_i) == stride(p_{i-1}) * extents().extent(p_{i-1}) for i in the
   range [1, rank_], where p_i is the i-th element of P.
3. Otherwise, false.

```cpp
template<class OtherMapping>
friend constexpr bool operator==(const mapping& x, const OtherMapping& y) noexcept;
```

**Constraints:**

1. layout-mapping-alike<OtherMapping> is satisfied.
2. rank_ == OtherMapping::extents_type::rank() is true.
3. OtherMapping::is_always_strided() is true.

**Preconditions:** OtherMapping meets the layout mapping requirements (24.7.3.4.3).

**Returns:** true if x.extents() == y.extents() is true, OFFSET(y) == 0 is true, and each of
x.stride(r) == y.stride(r) is true for r in the range [0, x.extents().rank()). Otherwise, false.
24.7.3.5 Accessor policy

24.7.3.5.1 General

An accessor policy defines types and operations by which a reference to a single object is created from an abstract data handle to a number of such objects and an index.

A range of indices \([0, N)\) is an accessible range of a given data handle and an accessor if, for each \(i\) in the range, the accessor policy’s access function produces a valid reference to an object.

In subclause 24.7.3.5.2,

1. \(A\) denotes an accessor policy.
2. \(a\) denotes a value of type \(A\) or const \(A\).
3. \(p\) denotes a value of type \(A::data\_handle\_type\) or const \(A::data\_handle\_type\).
   [Note 1: The type \(A::data\_handle\_type\) need not be dereferenceable. — end note]
4. \(n, i, j\) each denote values of type \(size\_t\).

24.7.3.5.2 Requirements

A type \(A\) meets the accessor policy requirements if

1. \(A\) models copyable,
2. \(is\_nothrow\_move\_constructible\_v<\!A\!>\) is true,
3. \(is\_nothrow\_move\_assignable\_v<\!A\!>\) is true,
4. \(is\_nothrow\_swappable\_v<\!A\!>\) is true, and
5. the following types and expressions are well-formed and have the specified semantics.

**typename A::element_type**

Result: A complete object type that is not an abstract class type.

**typename A::data_handle_type**

Result: A type that models copyable, and for which \(is\_nothrow\_move\_constructible\_v<\!A::data\_handle\_type\!>\) is true, \(is\_nothrow\_move\_assignable\_v<\!A::data\_handle\_type\!>\) is true, and \(is\_nothrow\_swappable\_v<\!A::data\_handle\_type\!>\) is true.
   [Note 1: The type of \(data\_handle\_type\) need not be \(element\_type\*\). — end note]

**typename A::reference**

Result: A type that models \(common\_reference\_with<\!A::reference\&\&\!, A::element\_type\&\!>\).
   [Note 2: The type of \(reference\) need not be \(element\_type\&\!). — end note]

**typename A::offset_policy**

Result: A type OP such that:

1. OP meets the accessor policy requirements,
2. \(constructible\_from<\!OP\!, const A\&\!>\) is modeled, and
3. \(is\_same\_v<\!typename OP::element\_type\!\!, typename A::element\_type\!>\) is true.

\(a\.access(p, i)\)

Result: \(A::reference\)

Remarks: The expression is equality preserving.

[Note 3: Concrete accessor policies can impose preconditions for their access function. However, they might not. For example, an accessor where \(p\) is \(span<A::element\_type\!, dynamic\_extent\!>\) and \(access(p, i)\) returns \(p[i \% p.size()]\) does not need to impose a precondition on \(i\). — end note]

\(a\.offset(p, i)\)

Result: \(A::offset\_policy::data\_handle\_type\)

Returns: \(q\) such that for \(b\) being \(A::offset\_policy(a)\), and any integer \(n\) for which \([0, n)\) is an accessible range of \(p\) and \(a\):
— $[0, n - i)$ is an accessible range of $q$ and $b$; and

— $b.\text{access}(q, j)$ provides access to the same element as $a.\text{access}(p, i + j)$, for every $j$ in the range $[0, n - i)$.

### Remarks: The expression is equality-preserving.

#### 24.7.3.5.3 Class template default_accessor

#### 24.7.3.5.3.1 Overview

```cpp
namespace std {
    template<class ElementType>
    struct default_accessor {
        using offset_policy = default_accessor;
        using element_type = ElementType;
        using reference = ElementType&;
        using data_handle_type = ElementType*;

        constexpr default_accessor() noexcept = default;
        template<class OtherElementType>
        constexpr default_accessor(default_accessor<OtherElementType>) noexcept;
        constexpr reference access(data_handle_type p, size_t i) const noexcept;
        constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;
    };
}
```

1. `default_accessor` meets the accessor policy requirements.
2. `ElementType` is required to be a complete object type that is neither an abstract class type nor an array type.
3. Each specialization of `default_accessor` is a trivially copyable type that models `semiregular`.
4. $[0, n]$ is an accessible range for an object $p$ of type `data_handle_type` and an object of type `default_accessor` if and only if $[p, p + n)$ is a valid range.

#### 24.7.3.5.3.2 Members

```cpp
template<class OtherElementType>
    constexpr default_accessor(default_accessor<OtherElementType>) noexcept {}
```

1. `Constraints: is_convertible_v<OtherElementType(*)[], element_type(*)[]>` is true.
2. `Effects: Equivalent to: return p[i];`
3. `Effects: Equivalent to: return p + i;`

#### 24.7.3.6 Class template mdspan

#### 24.7.3.6.1 Overview

```cpp
namespace std {
    template<class ElementType, class Extents, class LayoutPolicy = layout_right,
             class AccessorPolicy = default_accessor<ElementType>>
    class mdspan {
        public:
            using extents_type = Extents;
            using layout_type = LayoutPolicy;
            using accessor_type = AccessorPolicy;
            using mapping_type = typename layout_type::template mapping<extents_type>;
            using element_type = ElementType;
            using value_type = remove_cv_t<element_type>;
            using index_type = typename extents_type::index_type;
            using size_type = typename extents_type::size_type;
            using rank_type = typename extents_type::rank_type;
            using data_handle_type = typename accessor_type::data_handle_type;
            using reference = typename accessor_type::reference;
    }
}
```

§ 24.7.3.6.1
static constexpr rank_type rank() noexcept { return extents_type::rank(); }
static constexpr rank_type rank_dynamic() noexcept { return extents_type::rank_dynamic(); }
static constexpr size_t static_extent(rank_type r) noexcept { return extents_type::static_extent(r); }
constexpr index_type extent(rank_type r) const noexcept { return extents().extent(r); }

// 24.7.3.6.2, constructors
constexpr mdspan();
constexpr mdspan(const mdspan& rhs) = default;
constexpr mdspan(mdspan&& rhs) = default;

template<class... OtherIndexTypes>
constexpr explicit mdspan(data_handle_type ptr, OtherIndexTypes... exts);
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic())
    mdspan(data_handle_type p, span<OtherIndexType, N> exts);
template<class OtherIndexType, size_t N>

constexpr index_type stride(rank_type r) const
{ return map_.stride(r); }

private:
    accessor_type acc_;  // exposition only
    mapping_type map_;   // exposition only
    data_handle_type ptr_; // exposition only
};

template<class CArray>
requires (is_array_v<CArray> && rank_v<CArray> == 1)
mdspan(CArray&) -> mdspan<remove_all_extents_t<CArray>, extents<size_t, extent_v<CArray, 0>>;}

template<class Pointer>
requires (is_pointer_v<remove_reference_t<Pointer>>)
mdspan(Pointer&&) -> mdspan<remove_pointer_t<remove_reference_t<Pointer>>, extents<size_t>>;

template<class ElementType, class... Integrals>
requires ((is_convertible_v<Integrals, size_t> && ...) && sizeof...(Integrals) > 0)
explicit mdspan(ElementType*, Integrals...)
-> mdspan<ElementType, dextents<size_t, sizeof...(Integrals)>>;

template<class ElementType, class OtherIndexType, size_t N>
mdspan(ElementType*, span<OtherIndexType, N>)
-> mdspan<ElementType, dextents<size_t, N>>;

template<class ElementType, class OtherIndexType, size_t N>
mdspan(ElementType*, const array<OtherIndexType, N>&)
-> mdspan<ElementType, dextents<size_t, N>>;

template<class ElementType, class IndexType, size_t... ExtentsPack>
mdspan(ElementType*, const extents<IndexType, ExtentsPack...>&)
-> mdspan<ElementType, extents<IndexType, ExtentsPack...>>;

template<class ElementType, class MappingType>
mdspan(ElementType*, const MappingType&)
-> mdspan<ElementType, typename MappingType::extents_type,
    typename MappingType::layout_type>;

template<class MappingType, class AccessorType>
mdspan(const typename AccessorType::data_handle_type&, const MappingType&,
    const AccessorType&)
-> mdspan<typename AccessorType::element_type, typename MappingType::extents_type,
    typename MappingType::layout_type, AccessorType>;

Mandates:
(2.1) ElementType is a complete object type that is neither an abstract class type nor an array type,
(2.2) Extents is a specialization of extents, and
(2.3) is_same_v<ElementType, typename AccessorPolicy::element_type> is true.

LayoutPolicy shall meet the layout mapping policy requirements (24.7.3.4.3), and AccessorPolicy shall meet the accessor policy requirements (24.7.3.5.2).

Each specialization MDS of mdspan models copyable and
(4.1) is_nothrow_move_constructible_v<MDS> is true,
(4.2) is_nothrow_moveAssignable_v<MDS> is true, and
(4.3) is_nothrow_swappable_v<MDS> is true.

A specialization of mdspan is a trivially copyable type if its accessor_type, mapping_type, and data_handle_type are trivially copyable types.
§ 24.7.3.6.2 Constructors

```cpp
constexpr mdspan();
```

**Constraints:**

1. `rank_dynamic() > 0` is true.
2. `is_default_constructible_v<data_handle_type>` is true.
3. `is_default_constructible_v<mapping_type>` is true.
4. `is_default_constructible_v<accessor_type>` is true.

**Preconditions:** `[0, map_.required_span_size())` is an accessible range of `ptr_` and `acc_` for the values of `map_` and `acc_` after the invocation of this constructor.

**Effects:** Value-initializes `ptr_`, `map_`, and `acc_`.

```cpp
template<class... OtherIndexTypes>
constexpr explicit mdspan(data_handle_type p, OtherIndexTypes... exts);
```

Let `N` be `sizeof...(OtherIndexTypes)`.

**Constraints:**

1. `(is_convertible_v<OtherIndexTypes, index_type> && ...)` is true,
2. `(is_nothrow_constructible<index_type, OtherIndexTypes> && ...)` is true,
3. `N == rank() || N == rank_dynamic()` is true,
4. `is_constructible_v<mapping_type, extents_type>` is true, and
5. `is_default_constructible_v<accessor_type>` is true.

**Preconditions:** `[0, map_.required_span_size())` is an accessible range of `p` and `acc_` for the values of `map_` and `acc_` after the invocation of this constructor.

**Effects:**

1. Direct-non-list-initializes `ptr_` with `std::move(p)`,
2. Direct-non-list-initializes `map_` with `extents_type(static_cast<index_type>(std::move(exts))...)`, and

```cpp
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic()) mdspan(data_handle_type p, span<OtherIndexType, N> exts);
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic()) mdspan(data_handle_type p, const array<OtherIndexType, N>& exts);
```

**Constraints:**

1. `is_convertible_v<const OtherIndexType&, index_type>` is true,
2. `is_nothrow_constructible_v<index_type, const OtherIndexType&>` is true,
3. `N == rank() || N == rank_dynamic()` is true,
4. `is_constructible_v<mapping_type, extents_type>` is true, and
5. `is_default_constructible_v<accessor_type>` is true.

**Preconditions:** `[0, map_.required_span_size())` is an accessible range of `p` and `acc_` for the values of `map_` and `acc_` after the invocation of this constructor.

**Effects:**

1. Direct-non-list-initializes `ptr_` with `std::move(p)`,
2. Direct-non-list-initializes `map_` with `extents_type(exts)`, and
constexpr mdspan(data_handle_type p, const extents_type& ext);

Constraints:

- `is_constructible_v<mapping_type, const extents_type&>` is true, and
- `is_default_constructible_v<accessor_type>` is true.

Preconditions: `[0..map_.required_span_size()]` is an accessible range of `p` and `acc` for the values of `map` and `acc` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `ext`, and
- value-initializes `acc_`.

constexpr mdspan(data_handle_type p, const mapping_type& m);

Constraints: `is_default_constructible_v<accessor_type>` is true.

Preconditions: `[0..m.required_span_size()]` is an accessible range of `p` and `acc` for the value of `acc` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `m`, and
- value-initializes `acc_`.

constexpr mdspan(data_handle_type p, const mapping_type& m, const accessor_type& a);

Preconditions: `[0..m.required_span_size()]` is an accessible range of `p` and `a`.

Effects:

- Direct-non-list-initializes `ptr_` with `std::move(p)`,
- direct-non-list-initializes `map_` with `m`, and
- direct-non-list-initializes `acc_` with `a`.

template<class OtherElementType, class OtherExtents, class OtherLayoutPolicy, class OtherAccessor>
constexpr explicit(const mdspan<OtherElementType, OtherExtents, OtherLayoutPolicy, OtherAccessor>& other);

Constraints:

- `is_constructible_v<mapping_type, const OtherLayoutPolicy::template mapping<OtherExtents>&>` is true, and
- `is_constructible_v<accessor_type, const OtherAccessor&>` is true.

Mandates:

- `is_constructible_v<data_handle_type, const OtherAccessor::data_handle_type&>` is true, and
- `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions:

- For each rank index `r` of `extents_type`, `static_extent(r) == dynamic_extent || static_extent(r) == other.extent(r)` is true.
- `[0..map_.required_span_size()]` is an accessible range of `ptr` and `acc` for values of `ptr`, `map`, and `acc` after the invocation of this constructor.

Effects:

- Direct-non-list-initializes `ptr` with `other.ptr`,
- direct-non-list-initializes `map` with `other.map`, and
— direct-non-list-initializes \texttt{acc\_} with \texttt{other.\_acc\_.}

\textbf{Remarks:} The expression inside \texttt{explicit} is equivalent to:

\begin{verbatim}
!is_convertible_v<const OtherLayoutPolicy::template mapping<OtherExtents>&, mapping_type>
|| !is_convertible_v<const OtherAccessor&, accessor_type>
\end{verbatim}

### 24.7.3.6.3 Members

\begin{verbatim}
template<class... OtherIndexTypes>
constexpr reference operator[] (OtherIndexTypes... indices) const;
\end{verbatim}

#### Constraints

1. (1.1) \texttt{is\_convertible\_v<OtherIndexTypes, index\_type> \&\& \ldots} is true,
2. (1.2) \texttt{is\_nothrow\_constructible\_v<index\_type, OtherIndexTypes> \&\& \ldots} is true, and
3. (1.3) \texttt{sizeof...(OtherIndexTypes) \== rank() \is \textit{true}}.

#### Let I be \texttt{extents\_type::\_index\_cast(std::move(indices))}.

#### Preconditions: I is a multidimensional index in \texttt{extents\_}.

\textbf{[Note 1:} This implies that \texttt{map\_\_I \textless map\_.\_required\_span\_size() \is \textit{true}. — end note]\textbf{]}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
return acc\_.\_access(ptr\_, map\_(static\_cast<index\_type>(std::move(indices)))\ldots));
\end{verbatim}

\begin{verbatim}
template<class OtherIndexType>
constexpr reference operator[] (span<OtherIndexType, rank()> indices) const;
template<class OtherIndexType>
constexpr reference operator[] (const array<OtherIndexType, rank()> & indices) const;
\end{verbatim}

#### Constraints

1. (5.1) \texttt{is\_convertible\_v<const OtherIndexType&\_, index\_type> \is \textit{true}}
2. (5.2) \texttt{is\_nothrow\_constructible\_v<index\_type, const OtherIndexType&\_} is true.

\textbf{Effects:} Let \texttt{P} be a parameter pack such that

\begin{verbatim}
\texttt{is\_same\_v<make\_index\_sequence<rank\_>, index\_sequence<P\ldots>}}
\end{verbatim}

\texttt{\is \textit{true}. \textbf{Equivalent to:}}

\begin{verbatim}
return operator[](extents\_type::\_index\_cast(as\_const(indices\_[P])\ldots));
\end{verbatim}

\begin{verbatim}
constexpr size\_type size() const noexcept;
\end{verbatim}

\textbf{Preconditions:} The size of the multidimensional index space \texttt{extents\_} is representable as a value of \texttt{size\_type (6.8.2)}.

\textbf{Returns:} \texttt{extents\_fwd\_prod\_of\_extents(rank())}.

\begin{verbatim}
[[\textit{nodiscard}]] constexpr bool empty() const noexcept;
\end{verbatim}

\textbf{Returns:} \texttt{true} if the size of the multidimensional index space \texttt{extents\_} is 0, otherwise \texttt{false}.

\begin{verbatim}
friend constexpr void swap(mdspan\& x, mdspan\& y) noexcept;
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
swap(x.ptr\_, y.ptr\_);
swap(x.map\_, y.map\_);
swap(x.acc\_, y.acc\_);
\end{verbatim}

### 24.7.3.7 submdspan

#### Overview

The \texttt{submdspan} facilities create a new \texttt{mdspan} viewing a subset of elements of an existing input \texttt{mdspan}. The subset viewed by the created \texttt{mdspan} is determined by the \texttt{SliceSpecifier} arguments.

For each function defined in subclause 24.7.3.7 that takes a parameter pack named \texttt{slices} as an argument:

\begin{verbatim}
— let \texttt{index\_type} be
\end{verbatim}

\begin{verbatim}
— M::\texttt{index\_type} if the function is a member of a class \texttt{M},
\end{verbatim}
© ISO/IEC

2.1.2 — otherwise, \texttt{remove\_reference\_t<\texttt{decltype(src)}>::index\_type} if the function has a parameter named \texttt{src},

2.1.3 — otherwise, the same type as the function’s template argument \texttt{IndexType};

2.2 — let \texttt{rank} be the number of elements in \texttt{slices};

2.3 — let \( s_k \) be the \( k \)th element of \texttt{slices};

2.4 — let \( S_k \) be the type of \( s_k \); and

2.5 — let \texttt{map\_rank} be an \texttt{array<size\_t, \texttt{rank}>} such that for each \( k \) in the range \([0, \texttt{rank})\), \texttt{map\_rank}[k] equals:

2.5.1 — \texttt{dynamic\_extent} if \( S_k \) models \texttt{convertible\_to<index\_type>},

2.5.2 — otherwise, the number of types \( S_j \) with \( j < k \) that do not model \texttt{convertible\_to<index\_type>}.

24.7.3.7.2 \texttt{strided\_slice} 

\texttt{strided\_slice} represents a set of \texttt{extent} regularly spaced integer indices. The indices start at \texttt{offset}, and increase by increments of \texttt{stride}.

namespace std {
    template<class OffsetType, class ExtentType, class StrideType>
    struct strided\_slice {
        using offset\_type = OffsetType;
        using extent\_type = ExtentType;
        using stride\_type = StrideType;
        [[\texttt{no\_unique\_address}]] offset\_type offset{};
        [[\texttt{no\_unique\_address}]] extent\_type extent{};
        [[\texttt{no\_unique\_address}]] stride\_type stride{};
    };
}

\texttt{strided\_slice} has the data members and special members specified above. It has no base classes or members other than those specified.

3 \textit{Mandates:} \texttt{OffsetType}, \texttt{ExtentType}, and \texttt{StrideType} are signed or unsigned integer types, or model \texttt{integral\_constant\_like}.

[Note 1: \texttt{strided\_slice\{.offset = 1, .extent = 10, .stride = 3\}} indicates the indices 1, 4, 7, and 10. Indices are selected from the half-open interval \([1, 1 + 10)\). \textemdash \textit{end note}\]

24.7.3.7.3 \texttt{submdspan\_mapping\_result} 

Specializations of \texttt{submdspan\_mapping\_result} are returned by overloads of \texttt{submdspan\_mapping}.

namespace std {
    template<class Layout\_Mapping>
    struct submdspan\_mapping\_result {
        [[\texttt{no\_unique\_address}]] Layout\_Mapping mapping = Layout\_Mapping();
        size\_t offset{};
    };
}

\texttt{submdspan\_mapping\_result} has the data members and special members specified above. It has no base classes or members other than those specified.

3 \textit{Layout\_Mapping} shall meet the layout mapping requirements (24.7.3.4.3).

24.7.3.7.4 Exposition-only helpers 

\template<class T>
\texttt{constexpr T de\_ice(T val) \{ return val; \}}

\template<integral\_constant\_like T>
\texttt{constexpr auto de\_ice(T) \{ return T::value; \}}

\template<class Index\_Type, size\_t k, class... Slice\_Specifiers>
\texttt{constexpr Index\_Type first\_(Slice\_Specifiers... slices);} 

1 \textit{Mandates:} \texttt{Index\_Type} is a signed or unsigned integer type.
Let \( \phi_k \) denote the following value:

\begin{align*}
(2.1) & \quad s_k \text{ if } S_k \text{ models } \text{convertible_to<IndexType>}; \\
(2.2) & \quad \text{get<0>(} s_k \text{) if } S_k \text{ models } \text{index-pair-like<IndexType>}; \\
(2.3) & \quad \text{de-ice}(s_k.\text{offset}) \text{ if } S_k \text{ is a specialization of } \text{strided_slice}; \\
(2.4) & \quad \text{otherwise, } 0.
\end{align*}

**Preconditions**: \( \phi_k \) is representable as a value of type \text{IndexType}.

**Returns**: \text{extents<IndexType>::index-cast}(\phi_k).

```cpp
template<
size_t k,
class Extents, class... SliceSpecifiers
>
constexpr auto
last_(const Extents& src, SliceSpecifiers... slices);
```

**Mandates**: \text{Extents} is a specialization of \text{extents}.

Let \( \lambda_k \) denote the following value:

\begin{align*}
(7.1) & \quad \text{de-ice}(s_k) + 1 \text{ if } S_k \text{ models } \text{convertible_to<IndexType>}; \text{ otherwise} \\
(7.2) & \quad \text{get<1>(} s_k \text{) if } S_k \text{ models } \text{index-pair-like<IndexType>}; \text{ otherwise} \\
(7.3) & \quad \text{de-ice}(s_k.\text{offset}) + \text{de-ice}(s_k.\text{extent}) \text{ if } S_k \text{ is a specialization of } \text{strided_slice}; \text{ otherwise} \\
(7.4) & \quad \text{src.extent}(k).
\end{align*}

**Preconditions**: \( \lambda_k \) is representable as a value of type \text{index_type}.

**Returns**: \text{Extents::index-cast}(\lambda_k).

```cpp
template<class IndexType, size_t N, class... SliceSpecifiers>
constexpr array<IndexType, sizeof...(SliceSpecifiers)>
src_indices(const array<IndexType, N>& indices, SliceSpecifiers... slices);
```

**Mandates**: \text{IndexType} is a signed or unsigned integer type.

**Returns**: An \text{array<IndexType, sizeof...(SliceSpecifiers)>>} \text{src_idx} such that for each \( k \) in the range \([0, \text{sizeof...(SliceSpecifiers)})\), \text{src_idx}[k] equals

\begin{align*}
(11.1) & \quad \text{first_<IndexType, } k\text{>(slices...)} \text{ for each } k \text{ where } \text{map-rank}[k] \text{ equals } \text{dynamic_extent}, \\
(11.2) & \quad \text{otherwise, } \text{first_<IndexType, } k\text{>(slices...)} + \text{indices[map-rank}[k]].
\end{align*}

### 24.7.3.7.5 submdspan_extents function

```cpp
template<class IndexType, class... Extents, class... SliceSpecifiers>
constexpr auto submdspan_extents(const extents<IndexType, Extents...>& src,
                                  SliceSpecifiers... slices);
```

**Constraints**: \text{sizeof...(slices)} equals \text{Extents::rank()}. 

**Mandates**: For each rank index \( k \) of \text{src.extents()}, exactly one of the following is true:

\begin{align*}
(2.1) & \quad S_k \text{ models } \text{convertible_to<IndexType>}, \\
(2.2) & \quad S_k \text{ models } \text{index-pair-like<IndexType>}, \\
(2.3) & \quad \text{is_convertible_v<S_k, fullExtent_t> is true, or} \\
(2.4) & \quad S_k \text{ is a specialization of } \text{strided_slice}.
\end{align*}

**Preconditions**: For each rank index \( k \) of \text{src.extents()}, all of the following are true:

\begin{align*}
(3.1) & \quad \text{if } S_k \text{ is a specialization of } \text{strided_slice} \\
(3.1.1) & \quad s_k.\text{extent} = 0, \text{ or} \\
(3.1.2) & \quad s_k.\text{stride} > 0 \\
(3.2) & \quad 0 \leq \text{first_<IndexType, } k\text{>(slices...)} \leq \text{last_<k>(src, slices...)} \leq \text{src.extent}(k)
\end{align*}

Let \text{SubExtents} be a specialization of \text{extents} such that:

\begin{align*}
(4.1) & \quad \text{SubExtents::rank()} \text{ equals the number of } k \text{ such that } S_k \text{ does not model } \text{convertible_to<IndexType>}; \text{ and}
\end{align*}
for each rank index $k$ of $\text{Extents}$ such that $\text{map-rank}[k] \neq \text{dynamic_extent}$ is true, $\text{SubExtents}::\text{static_extent}(\text{map-rank}[k])$ equals:

- $\text{Extents}::\text{static_extent}(k)$ if $\text{is_convertible_v}<S_k, \text{full_extent_t}>$ is true; otherwise
- $\text{de-ice}(\text{tuple_element_t}<1,S_k>()) - \text{de-ice}(\text{tuple_element_t}<0,S_k>())$ if $S_k$ models $\text{index-pair-like}<\text{IndexType}>$, and both $\text{tuple_element_t}<0,S_k>$ and $\text{tuple_element_t}<1,S_k>$ model $\text{integral-constant-like}$; otherwise
- 0, if $S_k$ is a specialization of $\text{strided_slice}$, whose $\text{extent_type}$ models $\text{integral-constant-like}$, for which $\text{extent_type}()$ equals zero; otherwise
- $1 + (\text{de-ice}(S_k::\text{extent_type}()) - 1) / \text{de-ice}(S_k::\text{stride_type}())$, if $S_k$ is a specialization of $\text{strided_slice}$ whose $\text{extent_type}$ and $\text{stride_type}$ model $\text{integral-constant-like}$;
- otherwise, $\text{dynamic_extent}$.

Returns: A value $\text{ext}$ of type $\text{SubExtents}$ such that for each $k$ for which $\text{map-rank}[k] \neq \text{dynamic_extent}$ is true, $\text{ext.extent}(\text{map-rank}[k])$ equals:

- $s_k.\text{extent} == 0 \ ? 0 : 1 + (\text{de-ice}(s_k.\text{extent}) - 1) / \text{de-ice}(s_k.\text{stride})$ if $S_k$ is a specialization of $\text{strided_slice}$,
- otherwise, $\text{last}_<k>(\text{src}, \text{slices}) - \text{first}_<\text{IndexType}, k>(\text{slices})$.

24.7.3.7.6 Layout specializations of $\text{submdspan_mapping}$

```cpp
template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_left::mapping<Extents>::submdspan-mapping-impl(
    // exposition only
    SliceSpecifiers... slices) const -> see below;

template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_right::mapping<Extents>::submdspan-mapping-impl(
    // exposition only
    SliceSpecifiers... slices) const -> see below;

template<class Extents>
template<class... SliceSpecifiers>
constexpr auto layout_stride::mapping<Extents>::submdspan-mapping-impl(
    // exposition only
    SliceSpecifiers... slices) const -> see below;
```

Let $\text{index_type}$ be $\text{typename Extents::index_type}$.

Constraints: sizeof...(slices) equals Extents::rank().

Mandates: For each rank index $k$ of $\text{extents()}$, exactly one of the following is true:

- $S_k$ models $\text{convertible_to}<\text{index_type}>$,
- $S_k$ models $\text{index-pair-like}<\text{IndexType}>$,
- $\text{is_convertible_v}<S_k, \text{full_extent_t}>$ is true, or
- $S_k$ is a specialization of $\text{strided_slice}$.

Preconditions: For each rank index $k$ of $\text{extents()}$, all of the following are true:

- if $S_k$ is a specialization of $\text{strided_slice}$
  - $s_k.\text{extent} = 0$, or
  - $s_k.\text{stride} > 0$
- $0 \leq \text{first}_<\text{IndexType}, k>(\text{slices}) \leq \text{last}_<k>(\text{extents()}, \text{slices}) \leq \text{extents()}.\text{extent}(k)$

Let $\text{sub_ext}$ be the result of $\text{submdspan_extents}(\text{extents()}, \text{slices})$ and let $\text{SubExtents}$ be $\text{decltype(sub_ext)}$. 

§ 24.7.3.7.6
Let \( \text{sub\_strides} \) be an array\(<\text{SubExtents::index\_type}\), \text{SubExtents::rank()}\> such that for each rank index \( k \) of \text{extents()} \( \) for which \text{map\_rank}[k] is not \text{dynamic\_extent}, \text{sub\_strides}[\text{map\_rank}[k]] \) equals:

\[
\begin{align*}
\text{(6.1)} & \quad \text{stride}(k) \ast \text{de\_ice}(s_k.\text{stride}) \text{ if } S_k \text{ is a specialization of strided\_slice and } s_k.\text{stride} < s_k.\text{extent}; \\
\text{(6.2)} & \quad \text{otherwise, stride}(k).
\end{align*}
\]

Let P be a parameter pack such that \text{is\_same\_v<make\_index\_sequence<rank()>, index\_sequence<P...>}} is true.

Let \( \text{offset} \) be a value of type \text{size\_t} equal to \((\star\text{this})(\text{first\_<index\_type>, P...}(\text{slices}...))\).

**Returns:**

\[
\begin{align*}
\text{(9.1)} & \quad \text{submdspan\_mapping\_result}(\star\text{this}, 0), \text{if } \text{Extents::rank()} == 0 \text{ is true}; \\
\text{(9.2)} & \quad \text{otherwise, submdspan\_mapping\_result}(\text{layout\_left::mapping}(\text{sub\_ext}), \text{offset}), \text{if } \\
& \quad \text{layout\_type = layout\_left; and} \\
& \quad \text{for each } k \text{ in the range } [0, \text{SubExtents::rank()} - 1), \text{is\_convertible\_v}<S_k, \text{full\_extent\_t}> \text{ is true; and} \\
& \quad \text{for } k \text{ equal to } \text{SubExtents::rank()} - 1, S_k \text{ models index\_pair\_like<index\_type> or is\_convertible\_v}<S_k, \text{full\_extent\_t}> \text{ is true; } \\
& \quad \text{[Note 1: If the above conditions are true, all } S_k \text{ with } k \text{ larger than } \text{SubExtents::rank()} - 1 \text{ are convertible to index\_type].} \quad \text{—end note} \\
\text{(9.3)} & \quad \text{otherwise, submdspan\_mapping\_result}(\text{layout\_right::mapping}(\text{sub\_ext}), \text{offset}), \text{if } \\
& \quad \text{layout\_type = layout\_right; and} \\
& \quad \text{for each } k \text{ in the range } [\text{Extents::rank()} - \text{SubExtents::rank()} + 1, \text{Extents::rank()}), \text{is\_convertible\_v}<S_k, \text{full\_extent\_t}> \text{ is true; and} \\
& \quad \text{for } k \text{ equal to } \text{Extents::rank()} - \text{SubExtents::rank()}, S_k \text{ models index\_pair\_like<index\_type> or is\_convertible\_v}<S_k, \text{full\_extent\_t}> \text{ is true; } \\
& \quad \text{[Note 2: If the above conditions are true, all } S_k \text{ with } k < \text{Extents::rank()} - \text{SubExtents::rank()} \text{ are convertible to index\_type].} \quad \text{—end note} \\
\text{(9.4)} & \quad \text{otherwise, submdspan\_mapping\_result}(\text{layout\_stride::mapping}(\text{sub\_ext, sub\_strides}), \text{offset}).
\end{align*}
\]

**24.7.3.7.7 submdspan function template**

```
template<class ElementType, class Extents, class LayoutPolicy, 
class AccessorPolicy, class... SliceSpecifiers>
constexpr auto submdspan(
    const mdspan<ElementType, Extents, LayoutPolicy, AccessorPolicy>& src,
    SliceSpecifiers... slices) -> see below;
```

Let \( \text{index\_type} \) be typename \text{Extents::index\_type}.

Let \( \text{sub\_map\_offset} \) be the result of \text{submdspan\_mapping}(src.mapping(), slices...).

**Note 1:** This invocation of \text{submdspan\_mapping} selects a function call via overload resolution on a candidate set that includes the lookup set found by argument-dependent lookup (6.5.4). —end note

**Constraints:**

\[
\begin{align*}
\text{(3.1)} & \quad \text{sizeof...}(\text{slices}) \text{ equals Extents::rank()}, \text{and} \\
\text{(3.2)} & \quad \text{the expression submdspan\_mapping}(src.mapping(), \text{slices}...) \text{ is well-formed when treated as an unevaluated operand.}
\end{align*}
\]

**Mandates:**

\[
\begin{align*}
\text{(4.1)} & \quad \text{decltype(submdspan\_mapping}(src.mapping(), \text{slices}...)) \text{ is a specialization of submdspan\_mapping\_result.} \\
\text{(4.2)} & \quad \text{is\_same\_v<remove\_cvref_t<decltype(sub\_map\_offset.mapping.extents())>>, decltype(}
& \quad \text{submdspan\_extents(src.mapping(), \text{slices}...))> \text{ is true.}
\end{align*}
\]
For each rank index \( k \) of \( \text{src}.\text{extents()} \), exactly one of the following is true:

- \( S_k \) models `convertible_to<index_type>`,
- \( S_k \) models `index-pair-like<index_type>`,
- \( \text{is_convertible_v}<S_k, \text{full_extent_t}> \) is true, or
- \( S_k \) is a specialization of `strided_slice`.

Preconditions:

- For each rank index \( k \) of \( \text{src}.\text{extents()} \), all of the following are true:
  - if \( S_k \) is a specialization of `strided_slice`
    - \( s_k.\text{extent} = 0 \), or
    - \( s_k.\text{stride} > 0 \)
  - \( 0 \leq \text{first}_{<\text{index_type}, k>(\text{slices}...)} \leq \text{last}_{<k>}(\text{src}.\text{extents()}, \text{slices}...) \leq \text{src}.\text{extent}(k) \)
  - \( \text{sub_map_offset}.\text{mapping}.\text{extents}() == \text{submdspan_extents}(\text{src}.\text{mapping}(), \text{slices}...) \) is true; and
  - for each integer pack \( I \) which is a multidimensional index in \( \text{sub_map_offset}.\text{mapping}.\text{extents}() \),
    \[
    \text{sub_map_offset}.\text{mapping}(I...) + \text{sub_map_offset}.\text{offset} ==
    \text{src}.\text{mapping}()[\text{src-indices}(\text{array}{I...}, \text{slices}...)]
    \]
    is true.

[Note 2: These conditions ensure that the mapping returned by `submdspan_mapping` matches the algorithmically expected index-mapping given the slice specifiers. — end note]

Effects: Equivalent to:

```cpp
auto sub_map_offset = submdspan_mapping(src.mapping(), slices...);
return mdspan(src.accessor().offset(src.data(), sub_map_offset.offset),
              sub_map_offset.mapping,
              AccessorPolicy::offset_policy(src.accessor()));
```

Example 1: Given a rank-3 `mdspan grid3d` representing a three-dimensional grid of regularly spaced points in a rectangular prism, the function `zero_surface` sets all elements on the surface of the 3-dimensional shape to zero. It does so by reusing a function `zero_2d` that takes a rank-2 `mdspan`.

```cpp
// zero out all elements in an mdspan
template<class T, class E, class L, class A>
void zero_2d(mdspan<T, E, L, A> a) {
  static_assert(a.rank() == 2);
  for (int i = 0; i < a.extent(0); i++)
    for (int j = 0; j < a.extent(1); j++)
      a[i, j] = 0;
}

// zero out just the surface
template<class T, class E, class L, class A>
void zero_surface(mdspan<T, E, L, A> grid3d) {
  static_assert(grid3d.rank() == 3);
  zero_2d(submdspan(grid3d, 0, full_extent, full_extent));
  zero_2d(submdspan(grid3d, full_extent, 0, full_extent));
  zero_2d(submdspan(grid3d, full_extent, full_extent, 0));
  zero_2d(submdspan(grid3d, grid3d.extent(0) - 1, full_extent, full_extent));
  zero_2d(submdspan(grid3d, full_extent, grid3d.extent(1) - 1, full_extent));
  zero_2d(submdspan(grid3d, full_extent, full_extent, grid3d.extent(2) - 1));
}
```

— end example]
25 Iterators library

25.1 General

1 This Clause describes components that C++ programs may use to perform iterations over containers (Clause 24), streams (31.7), stream buffers (31.6), and other ranges (Clause 26).

2 The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 84.

Table 84 — Iterators library summary

template<class C> constexpr auto begin(C& c) noexcept(noexcept(std::begin(c))) -> decltype(std::begin(c));

template<class C> constexpr auto begin(const C& c) noexcept(noexcept(std::begin(c))) -> decltype(std::begin(c));

template<class C> constexpr auto end(C& c) noexcept(noexcept(std::end(c))) -> decltype(std::end(c));

template<class C> constexpr auto end(const C& c) noexcept(noexcept(std::end(c))) -> decltype(std::end(c));

template<class T, size_t N> constexpr T* rbegin(T (&array)[N]);

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);

template<class C> constexpr auto crbegin(const C& c) noexcept(noexcept(std::rbegin(c))) -> decltype(std::rbegin(c));

template<class C> constexpr auto crend(const C& c) noexcept(noexcept(std::rend(c))) -> decltype(std::rend(c));

template<class C> constexpr auto size(const C& c) noexcept(noexcept(c.size())) -> decltype(c.size());

template<class T, size_t N> constexpr size_t ssize(const T (&array)[N]) noexcept;

template<class C> [[nodiscard]] constexpr auto empty(const C& c) noexcept(noexcept(c.empty())) -> decltype(c.empty());

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;
25.3 Iterator requirements

25.3.1 In general

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator \( i \) supports the expression \(*i\), resulting in a value of some object type \( T \), called the value type of the iterator. An output iterator \( i \) has a non-empty set of types that are indirectly writable to the iterator; for each such type \( T \), the expression \(*i = o\) is valid where \( o \) is a value of type \( T \). For every iterator type \( X \), there is a corresponding signed integer-like type (25.3.4.4) called the difference type of the iterator.

Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: input iterators, output iterators, forward iterators, bidirectional iterators, random access iterators, and contiguous iterators, as shown in Table 85.

Table 85 — Relations among iterator categories

<table>
<thead>
<tr>
<th>Contiguous</th>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
</table>

The six categories of iterators correspond to the iterator concepts (3.1) input_iterator (25.3.4.9), (3.2) output_iterator (25.3.4.10), (3.3) forward_iterator (25.3.4.11), (3.4) bidirectional_iterator (25.3.4.12), (3.5) random_access_iterator (25.3.4.13), and (3.6) contiguous_iterator (25.3.4.14), respectively. The generic term iterator refers to any type that models the input_or_output_iterator concept (25.3.4.6).

Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

Iterators that further meet the requirements of output iterators are called mutable iterators. Nonmutable iterators are referred to as constant iterators.

In addition to the requirements in this subclause, the nested typedef-names specified in 25.3.2.3 shall be provided for the iterator type.

[Note 1: Either the iterator type must provide the typedef-names directly (in which case iterator_traits pick them up automatically), or an iterator_traits specialization must provide them. — end note]

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. Such a value is called a past-the-end value. Values of an iterator \( i \) for which the expression \(*i\) is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value,
the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the Cpp17DefaultConstructible requirements, using a value-initialized iterator as the source of a copy or move operation.

[Note 2: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — end note]

In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is an iterator and a sentinel that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.\(^{211}\)

An iterator and a sentinel denoting a range are comparable. A range \([i, s]\) is empty if \(i == s\); otherwise, \([i, s]\) refers to the elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the first iterator \(j\) such that \(j == s\).

A sentinel \(s\) is called reachable from an iterator \(i\) if and only if there is a finite sequence of applications of the expression ++\(i\) that makes \(i == s\). If \(s\) is reachable from \(i\), \([i, s]\) denotes a valid range.

A counted range \(i + [0, n]\) is empty if \(n == 0\); otherwise, \(i + [0, n]\) refers to the \(n\) elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the result of \(n\) applications of ++\(i\). A counted range \(i + [0, n]\) is valid if and only if \(n == 0\); or \(n\) is positive, \(i\) is dereferenceable, and ++\(i + [0, --n]\) is valid.

The result of the application of library functions to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

Destruction of an iterator may invalidate pointers and references previously obtained from that iterator if its type does not meet the Cpp17ForwardIterator requirements and does not model forward_iterator.

An invalid iterator is an iterator that may be singular.\(^{212}\)

Iterators are called constexpr iterators if all operations provided to meet iterator category requirements are constexpr functions.

[Note 3: For example, the types “pointer to int” and reverse_iterator<int*> are constexpr iterators. — end note]

### 25.3.2 Associated types

#### 25.3.2.1 Incrementable traits

To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if \(WI\) is the name of a type that models the weakly_incrementable concept (25.3.4.4), the type

\[
\text{iter_difference_t<WI>}
\]

be defined as the incrementable type’s difference type.

```cpp
namespace std {
    template<class> struct incrementable_traits { };

    template<class T>
    requires is_object_v<T>
    struct incrementable_traits<T> { 
        using difference_type = ptrdiff_t;
    };

    template<class I>
    struct incrementable_traits<const I>
    : incrementable_traits<I> { };
}
```

211) The sentinel denoting the end of a range can have the same type as the iterator denoting the beginning of the range, or a different type.

212) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.
template<class T>
    requires requires { typename T::difference_type; } 
struct incrementable_traits<T> {
    using difference_type = typename T::difference_type;
};

template<class T>
    requires (!requires { typename T::difference_type; } && 
        requires(const T& a, const T& b) { { a - b } -> integral; })
struct incrementable_traits<T> {
    using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
};

template<class T>
    using iter_difference_t = see below;

Let \( R \) be \( \text{remove.cvref}_t<I> \). The type \( \text{iter_difference}_t<I> \) denotes

\( (2.1) \quad \text{incrementable_traits<} R \text{>::difference_type if iterator_traits<} R \text{>::names a specialization generated from the primary template, and} \)

\( (2.2) \quad \text{iterator_traits<} R \text{>::difference_type otherwise.} \)

Users may specialize \text{incrementable_traits} on program-defined types.

### 25.3.2.2 Indirectly readable traits [readable.traits]

To implement algorithms only in terms of indirectly readable types, it is often necessary to determine the value type that corresponds to a particular indirectly readable type. Accordingly, it is required that if \( R \) is the name of a type that models the \text{indirectly_readable} concept (25.3.4.2), the type

\( \text{iter.value}_t<R> \)

be defined as the indirectly readable type’s value type.

#### 25.3.2.2.1 Indirectly readable traits

\( \text{cond.value}_t<T> \)

\( \text{cond.value}_t<T> \)

\( \text{has-member-value}_t \)

\( \text{has-member-element}_t \)

\( \text{indirectly_readable_traits} \)

\( \text{cond.value}_t<\text{typename T::value_type}> \)
template<has-member-element-type T>
struct indirectly_readable_traits<T>
  : cond-value-type<typename T::element_type> {};

template<has-member-value-type T>
requires has-member-element-type<T>
struct indirectly_readable_traits<T> {};

template<has-member-value-type T>
requires has-member-element-type<T> &&
  same_as<remove_cv_t<typename T::element_type>, remove_cv_t<typename T::value_type>>
struct indirectly_readable_traits<T>
  : cond-value-type<typename T::value_type> {};

template<class T> using iter_value_t = see below;

2 Let $R_I$ be remove_cvref_t$I$. The type $\text{iter\_value\_t}<I>$ denotes
   
   (2.1) — indirectly_readable_traits<$R_I$>::value_type if iterator_traits<$R_I$> names a specialization
generated from the primary template, and
   
   (2.2) — iterator_traits<$R_I$>::value_type otherwise.

3 Class template indirectly_readable_traits may be specialized on program-defined types.

4 [Note 1: Some legacy output iterators define a nested type named value_type that is an alias for void. These types
are not indirectly_readable and have no associated value types. — end note]

5 [Note 2: Smart pointers like shared_ptr<int> are indirectly_readable and have an associated value type, but a
smart pointer like shared_ptr<void> is not indirectly_readable and has no associated value type. — end note]

25.3.2.3 Iterator traits

To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator
category that corresponds to a particular iterator type. Accordingly, it is required that if $I$ is the type of an
iterator, the type

$$\text{iterator_traits}<I>::\text{iterator\_category}$$

be defined as the iterator's iterator category. In addition, the types

$$\text{iterator_traits}<I>::\text{pointer}$$
$$\text{iterator_traits}<I>::\text{reference}$$

shall be defined as the iterator's pointer and reference types; that is, for an iterator object $a$ of class
type, the same type as decltype(a.operator->() ) and decltype(*a), respectively. The type

$$\text{iterator\_traits}<I>::\text{pointer}$$

shall be void for an iterator of class type $I$ that does not support operator->. Additionally, in the case of an output iterator, the types

$$\text{iterator_traits}<I>::\text{value\_type}$$
$$\text{iterator_traits}<I>::\text{difference\_type}$$

may be defined as void.

2 The definitions in this subclause make use of the following exposition-only concepts:

```cpp
template<class I>
concept cpp17-iterator =
  requires(I i) {
    { *i } -> can-reference;
    { ++i } -> same_as<I&>;
    { *i++ } -> can-reference;
  } && copyable<I>;

template<class I>
concept cpp17-input-iterator =
  cpp17-iterator<I> && equality_comparable<I> && requires(I i) {
    typename incrementable_traits<I>::difference_type;
    typename indirectly_readable_traits<I>::value_type;
    typename common_reference_t<iter_reference_t<I>&&,
      typename indirectly_readable_traits<I>::value_type&>;```
typedef common_reference_t< decltype(*i++)&&, 
    typename indirectly_readable_traits<I>::value_type&; 
requires signed_integral<typename incrementable_traits<I>::difference_type>; 
};
template<class I> 
concept cpp17-forward_iterator = 
    cpp17-input_iterator<I> && constructible_from<I> && 
    is_reference_v<iter_reference_t<I>> && 
    same_as<remove_cvref_t<iter_reference_t<I>>, 
        typename indirectly_readable_traits<I>::value_type> && 
    requires(I i) { 
    { i++ } -> convertible_to<const I&>; 
    { *i++ } -> same_as<iter_reference_t<I>>; 
    };
template<class I> 
concept cpp17-bidirectional_iterator = 
    cpp17-forward_iterator<I> && requires(I i) { 
    { --i } -> same_as<I&>; 
    { i-- } -> convertible_to<const I&>; 
    { *i-- } -> same_as<iter_reference_t<I>>; 
    };
template<class I> 
concept cpp17-random-access_iterator = 
    cpp17-bidirectional_iterator<I> && totally_ordered<I> && 
    requires(I i, typename incrementable_traits<I>::difference_type n) { 
    { i += n } -> same_as<I&>; 
    { i -= n } -> same_as<I&>; 
    { i + n } -> same_as<I>; 
    { n + i } -> same_as<I>; 
    { i - n } -> same_as<I>; 
    { i - i } -> same_as<decltype(n)>; 
    { i[n] } -> convertible_to<iter_reference_t<I>>; 
    };

3 The members of a specialization iterator_traits<I> generated from the iterator_traits primary template are computed as follows:

(3.1) — If I has valid (13.10.3) member types difference_type, value_type, reference, and iterator_category, then iterator_traits<I> has the following publicly accessible members:

using iterator_category = typename I::iterator_category;
using value_type = typename I::value_type;
using difference_type = typename I::difference_type;
using pointer = see below;
using reference = see below;

If the qualified-id I::pointer is valid and denotes a type, then iterator_traits<I>::pointer names that type; otherwise, it names void.

(3.2) — Otherwise, if I satisfies the exposition-only concept cpp17-input_iterator, iterator_traits<I> has the following publicly accessible members:

using iterator_category = see below;
using value_type = typename indirectly_readable_traits<I>::value_type;
using difference_type = typename incrementable_traits<I>::difference_type;
using pointer = see below;
using reference = see below;

(3.2.1) — If the qualified-id I::pointer is valid and denotes a type, pointer names that type. Otherwise, if decltype(declval<I&>().operator->()) is well-formed, then pointer names that type. Otherwise, pointer names void.

(3.2.2) — If the qualified-id I::reference is valid and denotes a type, reference names that type. Otherwise, reference names iter_reference_t<I>.
If the qualified-id `I::iterator_category` is valid and denotes a type, `iterator_category` names that type. Otherwise, `iterator_category` names:

- random_access_iterator_tag if I satisfies `cpp17-random-access-iterator`, or otherwise
- bidirectional_iterator_tag if I satisfies `cpp17-bidirectional-iterator`, or otherwise
- forward_iterator_tag if I satisfies `cpp17-forward-iterator`, or otherwise
- input_iterator_tag.

Otherwise, if I satisfies the exposition-only concept `cpp17-iterator`, then `iterator_traits<I>` has the following publicly accessible members:

```cpp
using iterator_category = output_iterator_tag;
using value_type = void;
using difference_type = see below;
using pointer = void;
using reference = void;
```

If the qualified-id `incrementable_traits<I>::difference_type` is valid and denotes a type, then `difference_type` names that type; otherwise, it names `void`.

Otherwise, `iterator_traits<I>` has no members by any of the above names.

Explicit or partial specializations of `iterator_traits` may have a member type `iterator_concept` that is used to indicate conformance to the iterator concepts (25.3.4).

[Example 1: To indicate conformance to the `input_iterator` concept but a lack of conformance to the `Cpp17InputIterator` requirements (25.3.5.3), an `iterator_traits` specialization might have `iterator_concept` denote `input_iterator_tag` but not define `iterator_category`. —end example]

`iterator_traits` is specialized for pointers as

```cpp
namespace std {
    template<class T>
    requires is_object_v<T>
    struct iterator_traits<T*> {
        using iterator_concept = contiguous_iterator_tag;
        using iterator_category = random_access_iterator_tag;
        using value_type = remove_cv_t<T>;
        using difference_type = ptrdiff_t;
        using pointer = T*;
        using reference = T&;
    };
}
```

[Example 2: To implement a generic `reverse` function, a C++ program can do the following:

```cpp
template<class BI>
void reverse(BI first, BI last) {
    typename iterator_traits<BI>::difference_type n =
        distance(first, last);
    --n;
    while(n > 0) {
        typename iterator_traits<BI>::value_type
            tmp = *first;
        *first++ = *--last;
        *last = tmp;
        n -= 2;
    }
}
```

—end example]

25.3.3 Customization point objects

25.3.3.1 ranges::iter_move

The name `ranges::iter_move` denotes a customization point object (16.3.3.3.5). The expression `ranges::iter_move(E)` for a subexpression `E` is expression-equivalent to:
iter_move(E), if E has class or enumeration type and iter_move(E) is a well-formed expression when treated as an unevaluated operand, where the meaning of iter_move is established as-if by performing argument-dependent lookup only (6.5.4).

Otherwise, if the expression *E is well-formed:

- if *E is an lvalue, std::move(*E);
- otherwise, *E.

Otherwise, ranges::iter_move(E) is ill-formed.

[Note 1: This case can result in substitution failure when ranges::iter_move(E) appears in the immediate context of a template instantiation. — end note]

2 If ranges::iter_move(E) is not equal to *E, the program is ill-formed, no diagnostic required.

25.3.3.2 ranges::iter_swap
The name ranges::iter_swap denotes a customization point object (16.3.3.3.5) that exchanges the values (18.4.9) denoted by its arguments.

Let iter-exchange-move be the exposition-only function template:

```
template<class X, class Y>
constexpr iter_value_t<X> iter-exchange-move(X&& x, Y&& y)
noexcept(noexcept(iter_value_t<X>(iter_move(x))) &&
        noexcept(*x = iter_move(y)));
```

3 Effects: Equivalent to:

```
iter_value_t<X> old_value(iter_move(x));
*x = iter_move(y);
return old_value;
```

4 The expression ranges::iter_swap(E1, E2) for subexpressions E1 and E2 is expression-equivalent to:

- (void)iter_swap(E1, E2), if either E1 or E2 has class or enumeration type and iter_swap(E1, E2) is a well-formed expression with overload resolution performed in a context that includes the declaration
  template<class I1, class I2>
  void iter_swap(I1, I2) = delete;
  and does not include a declaration of ranges::iter_swap. If the function selected by overload resolution does not exchange the values denoted by E1 and E2, the program is ill-formed, no diagnostic required.

  [Note 1: This precludes calling unconstrained std::iter_swap. When the deleted overload is viable, program-defined overloads need to be more specialized (13.7.7.3) to be selected. — end note]

- Otherwise, if the types of E1 and E2 each model indirectly_readable, and if the reference types of E1 and E2 model swappable_with (18.4.9), then ranges::swap(*E1, *E2).

- Otherwise, if the types T1 and T2 of E1 and E2 model indirectly_movable_storable<T1, T2> and indirectly_movable_storable<T2, T1>, then (void)(*E1 = iter-exchange-move(E2, E1)), except that E1 is evaluated only once.

- Otherwise, ranges::iter_swap(E1, E2) is ill-formed.

  [Note 2: This case can result in substitution failure when ranges::iter_swap(E1, E2) appears in the immediate context of a template instantiation. — end note]

25.3.4 Iterator concepts

25.3.4.1 General
Otherwise, `ITER_CONCEPT(I)` does not denote a type.

2 [Note 1: `ITER_TRAITS` enables independent syntactic determination of an iterator's category and concept. — end note]

[Example 1:

```cpp
struct I {
    using value_type = int;
    using difference_type = int;

    int operator*() const;
    I& operator++();
    I operator++(int);
    I& operator--();
    I operator--(int);

    bool operator==(I) const;
};
```

`iterator_traits<I>::iterator_category` denotes `input_iterator_tag`, and `ITER_CONCEPT(I)` denotes `random_access_iterator_tag`. — end example]

25.3.4.2 Concept indirectly_readable

1 Types that are indirectly readable by applying `operator*` model the `indirectly_readable` concept, including pointers, smart pointers, and iterators.

```cpp
template<class In>
concept indirectly-readable-impl = // exposition only
    requires(const In in) {
        typename iter_value_t<In>;
        typename iter_reference_t<In>;
        typename iter_rvalue_reference_t<In>;
        { *in } -> same_as<iter_reference_t<In>>;
        { ranges::iter_move(in) } -> same_as<iter_rvalue_reference_t<In>>;
    } &&
    common_reference_with<iter_reference_t<In>&&, iter_value_t<In>&> &&
    common_reference_with<iter_reference_t<In>&&, iter_rvalue_reference_t<In>&&> &&
    common_reference_with<iter_rvalue_reference_t<In>&&, const iter_value_t<In>&>;
```

```cpp
template<class In>
concept indirectly_readable = indirectly-readable-impl<remove_cvref_t<In>>;
```

2 Given a value `i` of type `I`, `I` models `indirectly_readable` only if the expression `*i` is equality-preserving.

25.3.4.3 Concept indirectly_writable

1 The `indirectly_writable` concept specifies the requirements for writing a value into an iterator’s referenced object.

```cpp
template<class Out, class T>
concept indirectly_writable =
    requires(Out&& o, T&& t) {
        *o = std::forward<T>(t); // not required to be equality-preserving
        std::forward<Out>(o) = std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&>(*o) = std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&>(*std::forward<Out>(o)) =
            std::forward<T>(t); // not required to be equality-preserving
    };
```

2 Let `E` be an expression such that `decltype((E))` is `T`, and let `o` be a dereferenceable object of type `Out`. `Out` and `T` model `indirectly_writable<Out, T>` only if

(2.1) — If `Out` and `T` model `indirectly_readable<Out> && same_as<iter_value_t<Out>, decay_t<T>>`, then `*o` after any above assignment is equal to the value of `E` before the assignment.

3 After evaluating any above assignment expression, `o` is not required to be dereferenceable.

4 If `E` is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.4.6.15).
Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integral type of equal or greater width and the same signedness. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types do not exit via an exception. The result of such a conversion is the unique value of the destination type that is congruent to the source modulo \( 2^N \), where \( N \) is the width of the integer-class type.

Let \( a \) be an object of integer-class type \( I \), let \( b \) be an object of integer-class type \( I2 \) such that the expression \( b \) is implicitly convertible to \( I \), let \( x \) and \( y \) be, respectively, objects of type \( B(I) \) and \( B(I2) \) as described above that represent the same values as \( a \) and \( b \), and let \( c \) be an lvalue of any integral type.

For every integral type \( J \), let \( B(J) \) be the same type as \( J \).

Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integral type of equal or greater width and the same signedness. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types and between two integer-class types do not exit via an exception. The result of such a conversion is the unique value of the destination type that is congruent to the source modulo \( 2^N \), where \( N \) is the width of the destination type.
(7.2) The expressions ++@a, --@a, and @a shall be expression-equivalent to @a += 1, @a -= 1, and addressof(@a), respectively.

(7.3) For every unary-operator @ other than & for which the expression @x is well-formed, @a shall also be well-formed and have the same value, effects, and value category as @x. If @x has type bool, so too does @a; if @x has type B(I), then @a has type I.

(7.4) For every assignment operator @= for which c @= x is well-formed, c @= a shall also be well-formed and shall have the same values and effects as c @= x. The expression c @= a shall be an lvalue referring to c.

(7.5) For every assignment operator @= for which x @= y is well-formed, a @= b shall also be well-formed and shall have the same effects as x @= y, except that the value that would be stored into x is stored into a. The expression a @= b shall be an lvalue referring to a.

(7.6) For every non-assignment binary operator @ for which x @ y and y @ x are well-formed, a @ b and b @ a shall also be well-formed and shall have the same value, effects, and value category as x @ y and y @ x, respectively. If x @ y or y @ x has type B(I), then a @ b or b @ a, respectively, has type I; if x @ y or y @ x has type B(I2), then a @ b or b @ a, respectively, has type I2; if x @ y or y @ x has any other type, then a @ b or b @ a, respectively, has that type.

8 An expression E of integer-class type I is contextually convertible to bool as if by bool(E != I(0)).

9 All integer-class types model regular (18.6) and three-way_comparable<strong_ordering> (17.11.4).

10 A value-initialized object of integer-class type has value 0.

11 For every (possibly cv-qualified) integer-class type I, numeric_limits<I> is specialized such that each static data member m has the same value as numeric_limits<B(I)>::m, and each static member function f returns I(numeric_limits<B(I)>::f()).

12 For any two integer-like types I1 and I2, at least one of which is an integer-class type, common_type_t<I1, I2> denotes an integer-class type whose width is not less than that of I1 or I2. If both I1 and I2 are signed-integral-like types, then common_type_t<I1, I2> is also a signed-integral-like type.

13 is-integer-like<I> is true if and only if I is an integer-like type. is-signed-integer-like<I> is true if and only if I is a signed-integer-like type.

14 Let i be an object of type I. When i is in the domain of both pre- and post-increment, i is said to be incrementable. I models weakly_incrementable<I> only if

14.1 The expressions ++i and i++ have the same domain.

14.2 If i is incrementable, then both ++i and i++ advance i to the next element.

14.3 If i is incrementable, then addressof(++i) is equal to addressof(i).

15 Recommended practice: The implementaton of an algorithm on a weakly incrementable type should never attempt to pass through the same incrementable value twice; such an algorithm should be a single-pass algorithm.

[Note 3: For weakly_incrementable types, a equals b does not imply that ++a equals ++b. (Equality does not guarantee the substitution property or referential transparency.) Such algorithms can be used with istreams as the source of the input data through the istream_iterator class template. — end note]

25.3.4.5 Concept incrementable

The incrementable concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be equality_comparable.

[Note 1: This supersedes the annotations on the increment expressions in the definition of weakly_incrementable. — end note]

```cpp
template<class I>
concept incrementable =
    regular<I> &&
    weakly_incrementable<I> &&
    requires(I i) {
        { i++ } -> same_as<I>;
    };
```
2 Let $a$ and $b$ be incrementable objects of type $I$. $I$ models `incrementable` only if

(2.1) — If $\text{bool}(a == b)$ then $\text{bool}(a++ == b)$.

(2.2) — If $\text{bool}(a == b)$ then $\text{bool}((\text{void})a++, a) == ++b)$.

3 [Note 2: The requirement that $a$ equals $b$ implies $++a$ equals $++b$ (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model `incrementable`. — end note]

25.3.4.6 Concept `input_or_output_iterator`

1 The `input_or_output_iterator` concept forms the basis of the iterator concept taxonomy; every iterator models `input_or_output_iterator`. This concept specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to compare iterators with sentinels (25.3.4.7), to read (25.3.4.9) or write (25.3.4.10) values, or to provide a richer set of iterator movements (25.3.4.11, 25.3.4.12, 25.3.4.13).

```cpp
template<class I>
concept input_or_output_iterator =
    requires(I i) {
        *i
    } -> can-reference;

weakly_incrementable<I>;
```

[Note 1: Unlike the `Cpp17Iterator` requirements, the `input_or_output_iterator` concept does not require copyability. — end note]

25.3.4.7 Concept `sentinel_for`

1 The `sentinel_for` concept specifies the relationship between an `input_or_output_iterator` type and a `semiregular` type whose values denote a range.

```cpp
template<class S, class I>
concept sentinel_for =
    semiregular<S> &&
    input_or_output_iterator<I> &&
    weakly-equality-comparable-with<S, I>;
```

2 Let $s$ and $i$ be values of type $S$ and $I$ such that $[i, s)$ denotes a range. Types $S$ and $I$ model `sentinel_for<S, I>` only if

(2.1) — $i == s$ is well-defined.

(2.2) — If $\text{bool}(i != s)$ then $i$ is dereferenceable and $[+i, s)$ denotes a range.

(2.3) — assignable_from<I&, S> is either modeled or not satisfied.

3 The domain of $==$ is not static. Given an iterator $i$ and sentinel $s$ such that $[i, s)$ denotes a range and $i != s$, $i$ and $s$ are not required to continue to denote a range after incrementing any other iterator equal to $i$. Consequently, $i == s$ is no longer required to be well-defined.

25.3.4.8 Concept `sized_sentinel_for`

1 The `sized_sentinel_for` concept specifies requirements on an `input_or_output_iterator` type $I$ and a corresponding `sentinel_for<I>` that allow the use of the $-$ operator to compute the distance between them in constant time.

```cpp
template<class S, class I>
concept sized_sentinel_for =
    sentinel_for<S, I> &&
    !disable_sized_sentinel_for<remove_cv_t<S>, remove_cv_t<I>> &&
    requires(const I& i, const S& s) {
        { s - i } -> same_as<iter_difference_t<I>>;
        { i - s } -> same_as<iter_difference_t<I>>;
    };
```

2 Let $i$ be an iterator of type $I$, and $s$ a sentinel of type $S$ such that $[i, s)$ denotes a range. Let $N$ be the smallest number of applications of $++i$ necessary to make $\text{bool}(i == s)$ be `true`. $S$ and $I$ model `sized_sentinel_for<S, I>` only if

(2.1) — If $N$ is representable by `iter_difference_t<I>`, then $s - i$ is well-defined and equals $N$.

(2.2) — If $-N$ is representable by `iter_difference_t<I>`, then $i - s$ is well-defined and equals $-N$. § 25.3.4.8 1105
template<class S, class I>
constexpr bool disable_sized_sentinel_for = false;

Remarks: Pursuant to 16.4.5.2.1, users may specialize disable_sized_sentinel_for for cv-unqualified non-array object types S and I if S and/or I is a program-defined type. Such specializations shall be usable in constant expressions (7.7) and have type const bool.

[Note 1: disable_sized_sentinel_for allows use of sentinels and iterators with the library that satisfy but do not in fact model sized_sentinel_for. — end note]

[Example 1: The sized_sentinel_for concept is modeled by pairs of random_access_iterators (25.3.4.13) and by counted iterators and their sentinels (25.5.7.1). — end example]

25.3.4.9 Concept input_iterator

The input_iterator concept defines requirements for a type whose referenced values can be read (from the requirement for indirectly_readable (25.3.4.2)) and which can be both pre- and post-incremented.

[Note 1: Unlike the Cpp17InputIterator requirements (25.3.5.3), the input_iterator concept does not need equality comparison since iterators are typically compared to sentinels. — end note]

template<class I>
concept input_iterator =
input_or_output_iterator<I> &&
indirectly_readable<I> &&
requires { typename ITER_CONCEPT(I); } &&
derived_from<ITER_CONCEPT(I), input_iterator_tag>;

25.3.4.10 Concept output_iterator

The output_iterator concept defines requirements for a type that can be used to write values (from the requirement for indirectly_writable (25.3.4.3)) and which can be both pre- and post-incremented.

[Note 1: Output iterators are not required to model equality_comparable. — end note]

template<class I, class T>
concept output_iterator =
input_or_output_iterator<I> &&
indirectly_writable<I, T> &&
requires(I i, T&& t) {
  *i++ = std::forward<T>(t); // not required to be equality-preserving
};

Let E be an expression such that decltype((E)) is T, and let i be a dereferenceable object of type I. I and T model output_iterator<I, T> only if *i++ = E; has effects equivalent to:

*i = E;
++i;

Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

25.3.4.11 Concept forward_iterator

The forward_iterator concept adds copyability, equality comparison, and the multi-pass guarantee, specified below.

template<class I>
concept forward_iterator =
input_iterator<I> &&
derived_from<ITER_CONCEPT(I), forward_iterator_tag> &&
incrementable<I> &&
sentinel_for<I, I>;

The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type.

[Note 1: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]

Pointers and references obtained from a forward iterator into a range [i, s) shall remain valid while [i, s) continues to denote a range.

Two dereferenceable iterators a and b of type X offer the multi-pass guarantee if:
--- a == b implies ++a == ++b and
--- the expression ((void)[](X x){++x;}(a, *a)) is equivalent to the expression *a.

[Note 2: The requirement that a == b implies ++a == ++b and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators. — end note]

### 25.3.4.12 Concept bidirectional_iterator

The bidirectional_iterator concept adds the ability to move an iterator backward as well as forward.

```
template<class I>
concept bidirectional_iterator =
    forward_iterator<I> &&
    derived_from<ITER_CONCEPT(I), bidirectional_iterator_tag> &&
    requires(I i) {
        { --i } -> same_as<I&>;
        { i-- } -> same_as<I>;
    };
```

A bidirectional iterator r is decrementable if and only if there exists some q such that ++q == r. Decrementable iterators r shall be in the domain of the expressions --r and r--.

Let a and b be equal objects of type I. I models bidirectional_iterator only if:

1. If a and b are decrementable, then all of the following are true:
   a. addressof(--a) == addressof(a)
   b. bool(a-- == b)
   c. after evaluating both a-- and --b, bool(a == b) is still true
   d. bool(++(--a) == b)

2. If a and b are incrementable, then bool(--(++a) == b).

---

### 25.3.4.13 Concept random_access_iterator

The random_access_iterator concept adds support for constant-time advancement with +=, +, -=, and -, as well as the computation of distance in constant time with -. Random access iterators also support array notation via subscripting.

```
template<class I>
concept random_access_iterator =
    bidirectional_iterator<I> &&
    derived_from<ITER_CONCEPT(I), random_access_iterator_tag> &&
    totally_ordered<I> &&
    sized_sentinel_for<I, I> &&
    requires(I i, const I j, const iter_difference_t<I> n) {
        { i += n } -> same_as<I&>;
        { j + n } -> same_as<I>;
        { n + j } -> same_as<I>;
        { i -= n } -> same_as<I&>;
        { j - n } -> same_as<I>;
        { j[n] } -> same_as<iter_reference_t<I>>;
    };
```

Let a and b be valid iterators of type I such that b is reachable from a after n applications of ++a, let D be iter_difference_t<I>, and let n denote a value of type D. I models random_access_iterator only if

1. (a += n) is equal to b.
2. addressof(a += n) is equal to addressof(a).
3. (a + n) is equal to (a += n).
4. For any two positive values x and y of type D, if (a + D(x + y)) is valid, then (a + D(x + y)) is equal to ((a + x) + y).
5. (a + D(0)) is equal to a.
6. If (a + D(n - 1)) is valid, then (a + n) is equal to [](I c){ return ++c; }(a + D(n - 1)).
(2.7) \((b += D(-n))\) is equal to \(a\).
(2.8) \((b -= n)\) is equal to \(a\).
(2.9) \(\text{addressof}(b -= n)\) is equal to \(\text{addressof}(b)\).
(2.10) \((b - n)\) is equal to \((b -= n)\).
(2.11) If \(b\) is dereferenceable, then \(a[n]\) is valid and is equal to \(*b\).
(2.12) \(\text{bool}(a <= b)\) is true.

25.3.4.14 Concept contiguous_iterator

The contiguous_iterator concept provides a guarantee that the denoted elements are stored contiguously in memory.

```cpp
template<class I>
concept contiguous_iterator =
    random_access_iterator<I> &&
    derived_from<I, contiguous_iterator_tag> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>> &&
    requires(const I& i) {
        to_address(i) -> same_as<add_pointer_t<iter_reference_t<I>>>;
    };
```

Let \(a\) and \(b\) be dereferenceable iterators and \(c\) be a non-dereferenceable iterator of type \(I\) such that \(b\) is reachable from \(a\) and \(c\) is reachable from \(b\), and let \(D\) be \(\text{iter_difference_t}<I>\). The type \(I\) models contiguous_iterator only if

(2.1) \(\text{to_address}(a) == \text{addressof}(\*a)\),
(2.2) \(\text{to_address}(b) == \text{to_address}(a) + D(b - a)\),
(2.3) \(\text{to_address}(c) == \text{to_address}(a) + D(c - a)\),
(2.4) \(\text{ranges::iter_move}(a)\) has the same type, value category, and effects as \(\text{std::move}(\*a)\), and
(2.5) if \(\text{ranges::iter_swap}(a, b)\) is well-formed, it has effects equivalent to \(\text{ranges::swap}(\*a, \*b)\).

25.3.5 C++17 iterator requirements

In the following sections, \(a\) and \(b\) denote values of type \(X\) or \(\text{const } X\), \(n\) denotes a value of \(\text{difference_type}\), \(u\), \(\text{tmp}\), and \(m\) denote identifiers, \(r\) denotes a value of \(X\), \(t\) denotes a value of value type \(T\), \(o\) denotes a value of some type that is writable to the output iterator.

[Note 1: For an iterator type \(X\) there must be an instantiation of \(\text{iterator_traits}<X>\) (25.3.2.3). — end note]

25.3.5.2 Cpp17Iterator

The Cpp17Iterator requirements form the basis of the iterator taxonomy; every iterator meets the Cpp17Iterator requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read or write values, or to provide a richer set of iterator movements (25.3.5.3, 25.3.5.4, 25.3.5.6, 25.3.5.7).

A type \(X\) meets the Cpp17Iterator requirements if:

(2.1) \(X\) meets the Cpp17CopyConstructible, Cpp17CopyAssignable, Cpp17Swappable, and Cpp17Destructible requirements (16.4.4.2, 16.4.4.3), and
(2.2) \(\text{iterator_traits}<X>::\text{difference_type}\) is a signed integer type or void, and
(2.3) the expressions in Table 86 are valid and have the indicated semantics.

25.3.5.3 Input iterators

A class or pointer type \(X\) meets the requirements of an input iterator for the value type \(T\) if \(X\) meets the Cpp17Iterator (25.3.5.2) and Cpp17EqualityComparable (Table 28) requirements and the expressions in Table 87 are valid and have the indicated semantics.

In Table 87, the term the domain of \(==\) is used in the ordinary mathematical sense to denote the set of values over which \(==\) is (required to be) defined. This set can change over time. Each algorithm places additional...
Table 86 — *Cpp17Iterator* requirements

<table>

</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of `==` and `!=`.

*Example 1:* The call `find(a,b,x)` is defined only if the value of `a` has the property `p` defined as follows: `b` has property `p` and a value `i` has property `p` if (`*i==x`) or if (`*i!=x` and `++i` has property `p`). — *end example*

Table 87 — *Cpp17InputIterator* requirements (in addition to *Cpp17Iterator*)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>a != b</td>
<td>decltype(a != b)</td>
<td>!(a == b)</td>
<td>Preconditions: <code>(a,b)</code> is in the domain of <code>==</code>.</td>
</tr>
<tr>
<td>*a</td>
<td>reference, convertible to T</td>
<td></td>
<td>Preconditions: <code>a</code> is dereferenceable. The expression <code>(void)*a, *a</code> is equivalent to <code>*a</code>. If <code>a == b</code> and <code>(a,b)</code> is in the domain of <code>==</code> then <code>*a</code> is equivalent to <code>*b</code>.</td>
</tr>
<tr>
<td>a-&gt;m</td>
<td>(*a).m</td>
<td></td>
<td>Preconditions: <code>a</code> is dereferenceable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td>Preconditions: <code>r</code> is dereferenceable. <em>Postconditions:</em> <code>r</code> is dereferenceable or <code>r</code> is past-the-end; any copies of the previous value of <code>r</code> are no longer required to be dereferenceable nor to be in the domain of <code>==</code>. equivalent to (void)++r</td>
</tr>
<tr>
<td>*(void)r++</td>
<td>convertible to T</td>
<td>{ T tmp = *r; ++r; return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>

3 *Recommended practice:* The implementation of an algorithm on input iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single pass algorithm.
[Note 1: For input iterators, \(a == b\) does not imply \(++a == ++b\). (Equality does not guarantee the substitution property or referential transparency.) Value type \(T\) is not required to be a \(\text{Cpp17CopyAssignable}\) type (Table 34). Such an algorithm can be used with streams as the source of the input data through the \(\text{istream\_iterator}\) class template. — end note]

25.3.5.4 Output iterators

A class or pointer type \(X\) meets the requirements of an output iterator if \(X\) meets the \(\text{Cpp17Iterator}\) requirements (25.3.5.2) and the expressions in Table 88 are valid and have the indicated semantics.

Table 88 — \(\text{Cpp17OutputIterator}\) requirements (in addition to \(\text{Cpp17Iterator}\))

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>

<tbody>
<tr>
<td>(*r = o)</td>
<td>result is not used</td>
<td>Remarks: After this operation (r) is not required to be dereferenceable. Postconditions: (r) is incrementable.</td>
<td></td>
</tr>
<tr>
<td>(++r)</td>
<td>(X&amp;)</td>
<td>(\text{addressof}(r) == \text{addressof}(++r)). Remarks: After this operation (r) is not required to be dereferenceable. Postconditions: (r) is incrementable.</td>
<td></td>
</tr>
<tr>
<td>(r++)</td>
<td>convertible to (\text{const } X&amp;)</td>
<td>{ (X\ tmp = r; ++r; return tmp; } \text{ Remarks: After this operation } r \text{ is not required to be dereferenceable. Postconditions: } r \text{ is incrementable.}</td>
<td></td>
</tr>
<tr>
<td>(*r++ = o)</td>
<td>result is not used</td>
<td>Remarks: After this operation (r) is not required to be dereferenceable. Postconditions: (r) is incrementable.</td>
<td></td>
</tr>
</tbody>
</table>

2 Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

[Note 1: The only valid use of an \(\text{operator}\*\) is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Equality and inequality are not necessarily defined. — end note]

25.3.5.5 Forward iterators

A class or pointer type \(X\) meets the \(\text{Cpp17ForwardIterator}\) requirements if

1. \(X\) meets the \(\text{Cpp17InputIterator}\) requirements (25.3.5.3),
2. \(X\) meets the \(\text{Cpp17DefaultConstructible}\) requirements (16.4.4.2),
3. if \(X\) is a mutable iterator, \textit{reference} is a reference to \(T\); if \(X\) is a constant iterator, \textit{reference} is a reference to \textit{const} \(T\),
4. the expressions in Table 89 are valid and have the indicated semantics, and
5. objects of type \(X\) offer the multi-pass guarantee, described below.

The domain of \(==\) for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type.

[Note 1: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]
Two dereferenceable iterators \(a\) and \(b\) of type \(X\) offer the \textit{multi-pass guarantee} if:

\begin{equation}
\begin{align*}
& a == b \text{ implies } ++a == ++b \text{ and } \\
& X \text{ is a pointer type or the expression } (\text{void})++X(a), \text{ } *a \text{ is equivalent to the expression } *a.
\end{align*}
\end{equation}

[Note 2: The requirement that \(a == b\) implies \(++a == ++b\) (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]

Table 89 — \textit{Cpp17ForwardIterator} requirements (in addition to \textit{Cpp17InputIterator})

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>(r++)</td>
<td>convertible to (X) &amp;</td>
<td>{ (X) tmp = (r); &lt;br&gt; (++)tmp; }</td>
<td></td>
</tr>
<tr>
<td>(*r++)</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If \(a\) and \(b\) are equal, then either \(a\) and \(b\) are both dereferenceable or else neither is dereferenceable.

If \(a\) and \(b\) are both dereferenceable, then \(a == b\) if and only if \(*a\) and \(*b\) are bound to the same object.

25.3.5.6 Bidirectional iterators

A class or pointer type \(X\) meets the requirements of a bidirectional iterator if, in addition to meeting the \textit{Cpp17ForwardIterator} requirements, the following expressions are valid as shown in Table 90.

Table 90 — \textit{Cpp17BidirectionalIterator} requirements (in addition to \textit{Cpp17ForwardIterator})

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>(--r)</td>
<td>(X) &amp;</td>
<td></td>
<td>Preconditions: there exists (s) such that (r == ++s).&lt;br&gt;Postconditions: (r) is dereferenceable.&lt;br&gt;(--(++r) == r).&lt;br&gt;(--r == --s) implies (r == s).&lt;br&gt;addressof((r) == addressof(--r)).</td>
</tr>
<tr>
<td>(--r--)</td>
<td>convertible to (X) &amp;</td>
<td>{ (X) tmp = (r); &lt;br&gt;(--r; }</td>
<td></td>
</tr>
<tr>
<td>(*r--)</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[Note 1: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

25.3.5.7 Random access iterators

A class or pointer type \(X\) meets the requirements of a random access iterator if, in addition to meeting the \textit{Cpp17BidirectionalIterator} requirements, the following expressions are valid as shown in Table 91.
Table 91 — **Cpp17RandomAccessIterator** requirements (in addition to **Cpp17BidirectionalIterator**)  

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>r += n</code></td>
<td><code>X&amp;</code></td>
<td><code>{ difference_type m = n;</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>if (m &gt;= 0)</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>while (m--)</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>++r;</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>else</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>while (m++)</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>--r;</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>return r;</code></td>
<td></td>
</tr>
<tr>
<td><code>a + n</code></td>
<td><code>X</code></td>
<td><code>{ X tmp = a;</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>return tmp += n; }</code></td>
<td></td>

### 25.3.6 Indirect callable requirements

#### 25.3.6.1 General

There are several concepts that group requirements of algorithms that take callable objects (22.10.3) as arguments.

#### 25.3.6.2 Indirect callable traits

To implement algorithms taking projections, it is necessary to determine the projected type of an iterator’s value type. For the exposition-only alias template `indirect-value-t`, `indirect-value-t<T>` denotes

- `invoke_result_t<Proj&, indirect-value-t<i>>` if `T` names `projected<I, Proj>`, and
- `iter_value_t<T>&` otherwise.
The indirect callable concepts are used to constrain those algorithms that accept callable objects (22.10.3) as arguments.

```cpp
namespace std {
    template<class F, class I>
    concept indirectly_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        invocable<F, indirect-value-t<I>> &&
        invocable<F, iter_reference_t<I>> &&
        invocable<F, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F, indirect-value-t<I>>,
            invoke_result_t<F, iter_reference_t<I>>;}

    template<class F, class I>
    concept indirectly_regular_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        regular_invocable<F, indirect-value-t<I>> &&
        regular_invocable<F, iter_reference_t<I>> &&
        regular_invocable<F, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F, indirect-value-t<I>>,
            invoke_result_t<F, iter_reference_t<I>>;}

    template<class F, class I1, class I2>
    concept indirect_binary_predicate =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        predicate<F, indirect-value-t<I1>, indirect-value-t<I2>> &&
        predicate<F, indirect-value-t<I1>, iter_reference_t<I2>> &&
        predicate<F, iter_reference_t<I1>, indirect-value-t<I2>> &&
        predicate<F, iter_reference_t<I1>, iter_reference_t<I2>> &&
        predicate<F, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;}

    template<class F, class I1, class I2 = I1>
    concept indirect_equivalence_relation =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        equivalence_relation<F, indirect-value-t<I1>, indirect-value-t<I2>> &&
        equivalence_relation<F, indirect-value-t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F, iter_reference_t<I1>, indirect-value-t<I2>> &&
        equivalence_relation<F, iter_reference_t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;}

    template<class F, class I1, class I2 = I1>
    concept indirect_strict_weak_order =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        strict_weak_order<F, indirect-value-t<I1>, indirect-value-t<I2>> &&
        strict_weak_order<F, indirect-value-t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F, iter_reference_t<I1>, indirect-value-t<I2>> &&
        strict_weak_order<F, iter_reference_t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;}
```
25.3.6.4 Class template projected

Class template projected is used to constrain algorithms that accept callable objects and projections (3.42). It combines an indirectly_readable type I and a callable object type Proj into a new indirectly_readable type whose reference type is the result of applying Proj to the iter_reference_t of I.

```cpp
namespace std {
    template<class I, class Proj>
    struct projected_impl {
        // exposition only
        struct type {
            // exposition only
            using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
            using difference_type = iter_difference_t<I>;
            // present only if I models weakly_incrementable
            indirect_result_t<Proj&, I> operator*() const; // not defined
        };
    }

    template<indirectly_readable I, indirectly_regular_unary_invocable<I> Proj>
    using projected = projected_impl<I, Proj>::type;
}
```

25.3.7 Common algorithm requirements

25.3.7.1 General

There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between indirectly_readable and indirectly_writable types: indirectly_movable, indirectly_copyable, and indirectly_swappable. There are three relational concepts for rearrangements: permutable, mergeable, and sortable. There is one relational concept for comparing values from different sequences: indirectly_comparable.

1 [Note 1: The ranges::less function object type used in the concepts below imposes constraints on the concepts’ arguments in addition to those that appear in the concepts’ bodies (22.10.9). — end note]

25.3.7.2 Concept indirectly_movable

1 The indirectly_movable concept specifies the relationship between an indirectly_readable type and an indirectly_writable type between which values may be moved.

```cpp
template<class In, class Out>
concept indirectly_movable = indirectly_readable<In> && indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```

2 The indirectly_movable_storable concept augments indirectly_movable with additional requirements enabling the transfer to be performed through an intermediate object of the indirectly_readable type’s value type.

```cpp
template<class In, class Out>
concept indirectly_movable_storable = indirectly_movable<In, Out> && indirectly_writable<Out, iter_value_t<In>> && movable<iter_value_t<In>> && constructible_from<iter_value_t<In>>, iter_rvalue_reference_t<In>>& && assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

3 Let i be a dereferenceable value of type In. In and Out model indirectly_movable_storable<In, Out> only if after the initialization of the object obj in

```cpp
iter_value_t<In> obj(ranges::iter_move(i));
```

obj is equal to the value previously denoted by *i. If iter_value_reference_t<In> is an rvalue reference type, the resulting state of the value denoted by *i is valid but unspecified (16.4.6.15).

25.3.7.3 Concept indirectly_copyable

1 The indirectly_copyable concept specifies the relationship between an indirectly_readable type and an indirectly_writable type between which values may be copied.

§ 25.3.7.3

template<class In, class Out>
concept indirectly_copyable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_reference_t<In>>;

2 The indirectly_copyable_storable concept augments indirectly_copyable with additional requirements enabling the transfer to be performed through an intermediate object of the indirectly_readable type’s value type. It also requires the capability to make copies of values.

template<class In, class Out>
concept indirectly_copyable_storable =
    indirectly_copyable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>&> &&
    indirectly_writable<Out, const iter_value_t<In>&> &&
    indirectly_writable<Out, iter_value_t<In>&&> &&
    indirectly_writable<Out, const iter_value_t<In>&&> &&
    copyable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_reference_t<In>>&,
    assignably_from<iter_value_t<In>&, iter_reference_t<In>>;

Let \( i \) be a dereferenceable value of type \( In \). \( In \) and \( Out \) model indirectly_copyable_storable<In, Out> only if after the initialization of the object \( obj \) in

\[
\text{iter_value_t<In> obj(*i);}
\]

\( obj \) is equal to the value previously denoted by \( *i \). If \( \text{iter_reference_t<In>} \) is an rvalue reference type, the resulting state of the value denoted by \( *i \) is valid but unspecified (16.4.6.15).

25.3.7.4 Concept indirectly_swappable

The indirectly_swappable concept specifies a swappable relationship between the values referenced by two indirectly_readable types.

template<class I1, class I2 = I1>
concept indirectly_swappable =
    indirectly_readable<I1> && indirectly_readable<I2> &&
    requires(const I1 i1, const I2 i2) {
    ranges::iter_swap(i1, i1);
    ranges::iter_swap(i2, i2);
    ranges::iter_swap(i1, i2);
    ranges::iter_swap(i2, i1);
    }

25.3.7.5 Concept indirectly_comparable

The indirectly_comparable concept specifies the common requirements of algorithms that compare values from two different sequences.

template<class I1, class I2, class R, class P1 = identity,
    class P2 = identity>
concept indirectly_comparable =
    indirect_binary_predicate<R, projected<I1, P1>,
    projected<I2, P2>>;

25.3.7.6 Concept permutable

The permutable concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

template<class I>
concept permutable =
    forward_iterator<I> &&
    indirectly_movable_storable<I, I> &&
    indirectly_swappable<I, I>;

25.3.7.7 Concept mergeable

The mergeable concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.
template<class I1, class I2, class Out, class R = ranges::less,
         class P1 = identity, class P2 = identity>
concept mergeable =
    input_iterator<I1> &&
    input_iterator<I2> &&
    weakly_incrementable<Out> &&
    indirectly_copyable<I1, Out> &&
    indirectly_copyable<I2, Out> &&
    indirect_strict_weak_order<R, projected<I1, P1>, projected<I2, P2>>;

25.3.7.8 Concept sortable

The sortable concept specifies the common requirements of algorithms that permute sequences into ordered sequences (e.g., sort).

template<class I, class R = ranges::less, class P = identity>
concept sortable =
    permutable<I> &&
    indirect_strict_weak_order<R, projected<I, P>>;

25.4 Iterator primitives

25.4.1 General

To simplify the use of iterators, the library provides several classes and functions.

25.4.2 Standard iterator tags

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which are used as compile time tags for algorithm selection. They are: output_iterator_tag, input_iterator_tag, forward_iterator_tag, bidirectional_iterator_tag, random_access_iterator_tag, and contiguous_iterator_tag. For every iterator of type I, iterator_traits<I>::iterator_category shall be defined to be a category tag that describes the iterator’s behavior. Additionally, iterator_traits<I>::iterator_concept may be used to indicate conformance to the iterator concepts (25.3.4).

namespace std {
    struct output_iterator_tag { };  
    struct input_iterator_tag { };   
    struct forward_iterator_tag: public input_iterator_tag { };  
    struct bidirectional_iterator_tag: public forward_iterator_tag { };  
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };  
    struct contiguous_iterator_tag: public random_access_iterator_tag { };  
}

[Example 1: A program-defined iterator BinaryTreeIterator can be included into the bidirectional iterator category by specializing the iterator_traits template:]

template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
    using iterator_category = bidirectional_iterator_tag;
    using difference_type = ptrdiff_t;
    using value_type = T;
    using pointer = T*;
    using reference = T&;
};

—end example]

[Example 2: If evolve() is well-defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:]

template<class BidirectionalIterator>
inline void
    evolve(BidirectionalIterator first, BidirectionalIterator last) {  
    evolve(first, last,  
        typename iterator_traits<BidirectionalIterator>::iterator_category());  
}
template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
    bidirectional_iterator_tag) {
    // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
    random_access_iterator_tag) {
    // more efficient, but less generic algorithm
}

—end example

25.4.3 Iterator operations

Since only random access iterators provide + and − operators, the library provides two function templates advance and distance. These function templates use + and − for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

template<class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);

Preconditions: n is negative only for bidirectional iterators.

Effects: Increments i by n if n is non-negative, and decrements i by −n otherwise.

template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
    distance(InputIterator first, InputIterator last);

Preconditions: last is reachable from first, or InputIterator meets the Cpp17RandomAccessIterator requirements and first is reachable from last.

Effects: If InputIterator meets the Cpp17RandomAccessIterator requirements, returns (last − first); otherwise, increments first until last is reached and returns the number of increments.

template<class InputIterator>
constexpr InputIterator next(InputIterator x,
    typename iterator_traits<InputIterator>::difference_type n = 1);

Effects: Equivalent to: advance(x, n); return x;

template<class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x,
    typename iterator_traits<BidirectionalIterator>::difference_type n = 1);

Effects: Equivalent to: advance(x, −n); return x;

25.4.4 Range iterator operations

The library includes the function templates ranges::advance, ranges::distance, ranges::next, and ranges::prev to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type.

[Example 1: ranges::advance uses the + operator to move a random_access_iterator forward n steps in constant time. For an iterator type that does not model random_access_iterator, ranges::advance instead performs n individual increments with the ++ operator. —end example]

The function templates defined in 25.4.4 are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the postfix-expression in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

[Example 2:

void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1, 2, 3};
}
distance(begin(vec), end(vec));  // #1

The function call expression at #1 invokes std::ranges::distance, not std::distance, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::distance is more specialized (13.7.7.3) than std::ranges::distance since the former requires its first two parameters to have the same type. — end example]

The number and order of deducible template parameters for the function templates defined in 25.4.4 is unspecified, except where explicitly stated otherwise.

25.4.4.2 ranges::advance

template<input_or_output_iterator I>
constexpr void ranges::advance(I& i, iter_difference_t<I> n);

1 Preconditions: If I does not model bidirectional_iterator, n is not negative.

2 Effects:

(2.1) — If I models random_access_iterator, equivalent to i += n.
(2.2) — Otherwise, if n is non-negative, increments i by n.
(2.3) — Otherwise, decrements i by -n.

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr void ranges::advance(I& i, S bound);

3 Preconditions: Either assignable_from<I&, S> || sized_sentinel_for<S, I> is modeled, or [i, bound) denotes a range.

4 Effects:

(4.1) — If I and S model assignable_from<I&, S>, equivalent to i = std::move(bound).
(4.2) — Otherwise, if S and I model sized_sentinel_for<S, I>, equivalent to ranges::advance(i, bound - i).
(4.3) — Otherwise, while bool(i != bound) is true, increments i.

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);

5 Preconditions: If n > 0, [i, bound) denotes a range. If n == 0, [i,bound) or [bound,i) denotes a range. If n < 0, [bound,i) denotes a range, I models bidirectional_iterator, and I and S model same_as<I, S>.

6 Effects:

(6.1) — If S and I model sized_sentinel_for<S, I>:
(6.1.1) — If |n| ≥ |bound - i|, equivalent to ranges::advance(i, bound).
(6.1.2) — Otherwise, equivalent to ranges::advance(i, n).
(6.2) — Otherwise,
(6.2.1) — if n is non-negative, while bool(i != bound) is true, increments i but at most n times.
(6.2.2) — Otherwise, while bool(i != bound) is true, decrements i but at most -n times.

7 Returns: n - M, where M is the difference between the ending and starting positions of i.

25.4.4.3 ranges::distance

template<class I, sentinel_for<I> S>
requires (!sized_sentinel_for<S, I>)
constexpr iter_difference_t<I> ranges::distance(I first, S last);

1 Preconditions: [first,last) denotes a range.

2 Effects: Increments first until last is reached and returns the number of increments.
template<class I, sized_sentinel_for<decay_t<I>> S>
constexpr iter_difference_t<decay_t<I>> ranges::distance(I&& first, S last);

Effects: Equivalent to: return last - static_cast<const decay_t<I>&>(first);

template<range R>
constexpr range_difference_t<R> ranges::distance(R&& r);

Effects: If R models sized_range, equivalent to:
return static_cast<range_difference_t<R>>(ranges::size(r)); // 26.3.10
Otherwise, equivalent to:
return ranges::distance(ranges::begin(r), ranges::end(r)); // 26.3

25.4.4.4 ranges::next

template<input_or_output_iterator I>
constexpr I ranges::next(I x);

Effects: Equivalent to: ++x; return x;

template<input_or_output_iterator I>
constexpr I ranges::next(I x, iter_difference_t<I> n);

Effects: Equivalent to: ranges::advance(x, n); return x;

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, S bound);

Effects: Equivalent to: ranges::advance(x, bound); return x;

template<input_or_output_iterator I, sentinel_for<I> S>
constexpr I ranges::next(I x, iter_difference_t<I> n, S bound);

Effects: Equivalent to: ranges::advance(x, n, bound); return x;

25.4.4.5 ranges::prev

template<bidirectional_iterator I>
constexpr I ranges::prev(I x);

Effects: Equivalent to: --x; return x;

template<bidirectional_iterator I>
constexpr I ranges::prev(I x, iter_difference_t<I> n);

Effects: Equivalent to: ranges::advance(x, -n); return x;

template<bidirectional_iterator I>
constexpr I ranges::prev(I x, iter_difference_t<I> n, I bound);

Effects: Equivalent to: ranges::advance(x, -n, bound); return x;

25.5 Iterator adaptors

25.5.1 Reverse iterators

25.5.1.1 General

Class template reverse_iterator is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

25.5.1.2 Class template reverse_iterator

namespace std {
    template<class Iterator>
    class reverse_iterator {
    public:
        using iterator_type = Iterator;
        using iterator_concept = see below;
        using iterator_category = see below;
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;
    }
using pointer = typename iterator_traits<Iterator>::pointer;
using reference = iter_reference_t<Iterator>;
constexpr reverse_iterator();
constexpr explicit reverse_iterator(Iterator x);
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);

constexpr Iterator base() const;
constexpr reference operator*() const;
constexpr pointer operator->() const requires see below;
constexpr reverse_iterator& operator++();
constexpr reverse_iterator operator++(int);
constexpr reverse_iterator& operator--();
constexpr reverse_iterator operator--(int);
constexpr reverse_iterator operator+ (difference_type n) const;
constexpr reverse_iterator& operator+=(difference_type n);
constexpr reverse_iterator operator- (difference_type n) const;
constexpr reverse_iterator& operator-=(difference_type n);
constexpr unspecified operator[](difference_type n) const;
friend constexpr iter_rvalue_reference_t<Iterator> iter_move(const reverse_iterator& i) noexcept(see below);
template<indirectly_swappable<Iterator> Iterator2> friend constexpr void iter_swap(const reverse_iterator& x, const reverse_iterator<Iterator2>& y) noexcept(see below);

protected:
  Iterator current;
};

1 The member typedef-name iterator_concept denotes
   — random_access_iterator_tag if Iterator models random_access_iterator, and
   — bidirectional_iterator_tag otherwise.

2 The member typedef-name iterator_category denotes
   — random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models derived_from<random_access_iterator_tag>, and
   — iterator_traits<Iterator>::iterator_category otherwise.

25.5.1.3 Requirements [reverse.iter.requirements]

1 The template parameter Iterator shall either meet the requirements of a Cpp17BidirectionalIterator (25.3.5.6) or model bidirectional_iterator (25.3.4.12).

2 Additionally, Iterator shall either meet the requirements of a Cpp17RandomAccessIterator (25.3.5.7) or model random_access_iterator (25.3.4.13) if the definitions of any of the members
   — operator+, operator-, operator+=, operator-= (25.5.1.7), or
   — operator[] (25.5.1.6),
   or the non-member operators (25.5.1.8)
   — operator<, operator<=, operator>=, operator-, or operator+ (25.5.1.9)
   are instantiated (13.9.2).

25.5.1.4 Construction and assignment [reverse.iter.cons]
```cpp
constexpr reverse_iterator();

**Effects:** Value-initializes `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```cpp
constexpr explicit reverse_iterator(Iterator x);

**Effects:** Initializes `current` with `x`.

```cpp
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);

**Constraints:** `is_same_v<U, Iterator>` is `false` and `const U&` models `convertible_to<Iterator>`. 

**Effects:** Initializes `current` with `u.current`.

```cpp
template<class U> constexpr reverse_iterator&
operator=(const reverse_iterator<U>& u);

**Constraints:** `is_same_v<U, Iterator>` is `false`, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

**Effects:** Assigns `u.current` to `current`.

**Returns:** `*this`.

### 25.5.1.5 Conversion [reverse.iter.conv]

```cpp
constexpr Iterator base() const;

**Returns:** `current`.

### 25.5.1.6 Element access [reverse.iter.elem]

```cpp
constexpr reference operator*() const;

**Effects:** As if by:

```cpp
Iterator tmp = current;
return *--tmp;
```

```cpp
constexpr pointer operator->() const
requires (is_pointer_v<Iterator> ||
  requires(const Iterator i) { i.operator->(); });
```

**Effects:**

-(2.1) If `Iterator` is a pointer type, equivalent to: return `prev(current)`;

-(2.2) Otherwise, equivalent to: return `prev(current).operator->()`;

```cpp
constexpr unspecified operator[](difference_type n) const;

**Returns:** `current[-n-1]`.

### 25.5.1.7 Navigation [reverse.iter.nav]

```cpp
constexpr reverse_iterator operator+(difference_type n) const;

**Returns:** `reverse_iterator(current-n)`.

```cpp
constexpr reverse_iterator operator-(difference_type n) const;

**Returns:** `reverse_iterator(current+n)`.

```cpp
constexpr reverse_iterator& operator++();

**Effects:** As if by: `--current`;

**Returns:** `*this`.

```cpp
constexpr reverse_iterator operator++(int);

**Effects:** As if by:

```cpp
reverse_iterator tmp = *this;
```
constexpr reverse_iterator& operator--();

Effects: As if by ++current.

Returns: *this.

constexpr reverse_iterator operator--(int);

Effects: As if by:
reverse_iterator tmp = *this;
++current;
return tmp;

constexpr reverse_iterator& operator+=(difference_type n);

Effects: As if by:
current -= n;

Returns: *this.

cstexpr reverse_iterator& operator-=(difference_type n);

Effects: As if by: current += n;

Returns: *this.

25.5.1.8 Comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() != y.base() is well-formed and convertible to bool.

Returns: x.base() != y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.

Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() >= y.base() is well-formed and convertible to bool.

Returns: x.base() >= y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() > y.base() is well-formed and convertible to bool.

Returns: x.base() > y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Constraints: x.base() >= y.base() is well-formed and convertible to bool.

Returns: x.base() >= y.base().
template<class Iterator1, class Iterator2>
  constexpr bool operator>=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Constraints: \( x.\text{base}() \leq y.\text{base}() \) is well-formed and convertible to \textit{bool}.

Returns: \( x.\text{base}() \leq y.\text{base}() \).

template<class Iterator1, class Iterator2>
  constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const reverse_iterator<Iterator1>& x,
            const reverse_iterator<Iterator2>& y);

Returns: \( y.\text{base}() \llt x.\text{base}() \).

[\textit{Note 1}: The argument order in the \textit{Returns} element is reversed because this is a reverse iterator. — end note]

25.5.1.9 Non-member functions

template<class Iterator1, class Iterator2>
  constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

Returns: \( y.\text{base}() - x.\text{base}() \).

template<class Iterator1, class Iterator2>
  constexpr reverse_iterator<Iterator1> operator+(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y)
  {(int) decltype(y.base() - x.base());

Returns: reverse_iterator<Iterator1>(x.base() - n).

friend constexpr iter_rvalue_reference_t<Iterator> iter_move(const reverse_iterator& i) noexcept;

Effects: Equivalent to:

auto tmp = i.base();
return ranges::iter_move(--tmp);

Remarks: The exception specification is equivalent to:

\textit{is_nothrow_copy_constructible_v<Iterator> &&
noexcept(ranges::iter_moves(range::iter_move(--declval<Iterator&>()), ())})

friend constexpr void iter_swap(const reverse_iterator& x,
                               const reverse_iterator<Iterator2>& y) noexcept;

Effects: Equivalent to:

auto xtmp = x.base();
auto ytmp = y.base();
ranges::iter_swap(--xtmp, --ytmp);

Remarks: The exception specification is equivalent to:

\textit{is_nothrow_copy_constructible_v<Iterator> &&
is_nothrow_copy_constructible_v<Iterator2> &&
noexcept(ranges::iter_moves(range::iter_move(--declval<Iterator&>()), --declval<Iterator2&>()))}

template<class Iterator>
  constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);

Returns: reverse_iterator<Iterator>(i).

25.5.2 Insert iterators

25.5.2.1 General

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called \textit{insert iterators}, are provided in the library. With regular iterator classes,
while (first != last) *result++ = *first++;
causes a range \([\text{first}, \text{last})\) to be copied into a range starting with result. The same code with result
being an insert iterator will insert corresponding elements into the container. This device allows all of the
copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where
insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators
meet the requirements of output iterators. \texttt{operator*} returns the insert iterator itself. The assignment
\texttt{operator=(const T& x)} is defined on insert iterators to allow writing into them, it inserts \texttt{x} right before
where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the
container where the insertion takes place. \texttt{back_insert_iterator} inserts elements at the end of a container,
\texttt{front_insert_iterator} inserts elements at the beginning of a container, and \texttt{insert_iterator} inserts
elements where the iterator points to in a container. \texttt{back_inserter}, \texttt{front_inserter}, and \texttt{inserter}
are three functions making the insert iterators out of a container.

### 25.5.2.2 Class template \texttt{back_insert_iterator}

namespace std {
    template<class Container>
    class back_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        constexpr explicit back_insert_iterator(Container& x);
        constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
        constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
        constexpr back_insert_iterator& operator*();
        constexpr back_insert_iterator& operator++();
        constexpr back_insert_iterator operator++(int);
    }
}

#### 25.5.2.2.1 Operations

```cpp
constexpr explicit back_insert_iterator(Container& x);
1  Effects: Initializes \texttt{container} with addressof(x).

constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
2  Effects: As if by: \texttt{container->push_back(value)};
3  Returns: *this.

constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
4  Effects: As if by: \texttt{container->push_back(std::move(value))};
5  Returns: *this.

constexpr back_insert_iterator& operator*();
6  Returns: *this.

constexpr back_insert_iterator& operator++();
constexpr back_insert_iterator& operator++(int);
7  Returns: *this.
```
25.5.2.2 \textbf{back\_inserter}

\begin{verbatim}
template<class Container>
constexpr back_insert_iterator<Container> back_inserter(Container& x);
\end{verbatim}

1 \textit{Returns}: $\text{back\_insert\_iterator<Container>}(x)$.

25.5.2.3 \textbf{Class template front\_insert\_iterator}

\begin{verbatim}
namespace std {
    template<class Container>
    class front_insert_iterator {
        protected:
            Container* container;

        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using container_type = Container;

            constexpr explicit front_insert_iterator(Container& x);
            constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
            constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
            constexpr front_insert_iterator& operator*();
            constexpr front_insert_iterator& operator++();
            constexpr front_insert_iterator operator++(int);
    };
}
\end{verbatim}

25.5.2.3.1 \textbf{Operations}

\begin{verbatim}
constexpr explicit front_insert_iterator(Container& x);
\end{verbatim}

1 \textit{Effects}: Initializes \texttt{container} with \texttt{addressof(x)}.

\begin{verbatim}
constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
\end{verbatim}

2 \textit{Effects}: As if by: \texttt{container->push\_front(value)};

3 \textit{Returns}: *this.

\begin{verbatim}
constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
\end{verbatim}

4 \textit{Effects}: As if by: \texttt{container->push\_front(std::move(value))};

5 \textit{Returns}: *this.

\begin{verbatim}
constexpr front_insert_iterator& operator*();
\end{verbatim}

6 \textit{Returns}: *this.

\begin{verbatim}
constexpr front_insert_iterator& operator++();
\end{verbatim}

7 \textit{Returns}: *this.

25.5.2.3.2 \textbf{front\_inserter}

\begin{verbatim}
template<class Container>
constexpr front_insert_iterator<Container> front_inserter(Container& x);
\end{verbatim}

1 \textit{Returns}: $\text{front\_insert\_iterator<Container>}(x)$.

25.5.2.4 \textbf{Class template insert\_iterator}

\begin{verbatim}
\end{verbatim}

§ 25.5.2.4
namespace std {

template<class Container>
class insert_iterator {

protected:
  Container* container;
  ranges::iterator_t<Container> iter;

public:
  using iterator_category = output_iterator_tag;
  using value_type = void;
  using difference_type = ptrdiff_t;
  using pointer = void;
  using reference = void;
  using container_type = Container;

  constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
  constexpr insert_iterator& operator=(const typename Container::value_type& value);
  constexpr insert_iterator& operator=(typename Container::value_type&& value);
  constexpr insert_iterator& operator*();
  constexpr insert_iterator& operator++();
  constexpr insert_iterator& operator++(int);
};
}

25.5.2.4.1 Operations
[insert.iter.ops]

constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
1 Effects: Initializes container with addressof(x) and iter with i.

constexpr insert_iterator& operator=(const typename Container::value_type& value);
2 Effects: As if by:
  iter = container->insert(iter, value);
  ++iter;
3 Returns: *this.

constexpr insert_iterator& operator=(typename Container::value_type&& value);
4 Effects: As if by:
  iter = container->insert(iter, std::move(value));
  ++iter;
5 Returns: *this.

constexpr insert_iterator& operator*();
6 Returns: *this.

constexpr insert_iterator& operator++();
constexpr insert_iterator& operator++(int);
7 Returns: *this.

25.5.2.4.2 inserter
[inserter]

template<class Container>
constexpr insert_iterator<Container> inserter(Container& x, ranges::iterator_t<Container> i);
1 Returns: insert_iterator<Container>(x, i).

25.5.3 Constant iterators and sentinels
[const.iterators]

25.5.3.1 General
[const.iterators.general]
1 Class template basic_const_iterator is an iterator adaptor with the same behavior as the underlying
  iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s

§ 25.5.3.1

1126
indirection operator to a type such that the adapted iterator is a constant iterator (25.3). Some generic
algorithms can be called with constant iterators to avoid mutation.

2 Specializations of basic_const_iterator are constant iterators.

25.5.3.2 Alias templates

```cpp
template<indirectly_readable It>
using iter_const_reference_t =
    common_reference_t<const iter_value_t<It>&&, iter_reference_t<It>>;

template<class It>
concept constant_iterator =
    // exposition only
    input_iterator<It> && same_as<iter_const_reference_t<It>, iter_reference_t<It>>;

template<input_iterator I>
using const_iterator =
    see below;

1 Result: If I models constant_iterator, I. Otherwise, basic_const_iterator<I>.

template<semiregular S>
using const_sentinel =
    see below;

2 Result: If S models input_iterator, const_iterator<S>. Otherwise, S.
```

25.5.3.3 Class template basic_const_iterator

```cpp
namespace std {
    template<class I>
    concept not_a_const_iterator =
        see below; // exposition only

    template<indirectly_readable I>
    using iter_const_rvalue_reference_t =
        // exposition only
        common_reference_t<const iter_value_t<I>&&, iter_rvalue_reference_t<I>>;

    template<input_iterator Iterator>
    class basic_const_iterator {
        Iterator current_ = Iterator();
        using reference = iter_const_reference_t<Iterator>; // exposition only
        using rvalue_reference =
            // exposition only
            iter_const_rvalue_reference_t<Iterator>;

    public:
        using iterator_concept = see below;
        using iterator_category = see below; // not always present
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;

        basic_const_iterator() requires default_initializable<Iterator> = default;
        constexpr basic_const_iterator(Iterator current);
        template<convertible_to<Iterator> U>
        constexpr basic_const_iterator(basic_const_iterator<U> current);
        template<different-from basic_const_iterator T>
            requires convertible_to<T, Iterator>
        constexpr basic_const_iterator(T&& current);

        constexpr const Iterator& base() const & noexcept;
        constexpr Iterator base() &&;
        constexpr reference operator*() const;
        constexpr rvalue_reference operator->() const
            requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&
            same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;

        constexpr basic_const_iterator& operator++();
        constexpr void operator++(int);
        constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;
    }
```
constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;
constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;

constexpr basic_const_iterator& operator+=(difference_type n) requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n) requires random_access_iterator<Iterator>;
constexpr reference operator[](difference_type n) const requires random_access_iterator<Iterator>;

template<sentinel_for<Iterator> S>
constexpr bool operator==(const S& s) const;

template<not-a-const-iterator CI>
requires constant_iterator<CI> && convertible_to<Iterator const&, CI>
constexpr operator CI() const &;

template<not-a-const-iterator CI>
requires constant_iterator<CI> && convertible_to<Iterator, CI>
constexpr operator CI() &&;

constexpr bool operator<(const basic_const_iterator& y) const requires random_access_iterator<Iterator>;
constexpr bool operator>(const basic_const_iterator& y) const requires random_access_iterator<Iterator>;
constexpr bool operator<=(const basic_const_iterator& y) const requires random_access_iterator<Iterator>;
constexpr bool operator>=(const basic_const_iterator& y) const requires random_access_iterator<Iterator>;
constexpr auto operator<=>(const basic_const_iterator& y) const requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;

template<different-from<basic_const_iterator> I>
constexpr bool operator<(const I& y) const requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<different-from<basic_const_iterator> I>
constexpr bool operator>(const I& y) const requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<different-from<basic_const_iterator> I>
constexpr bool operator<=(const I& y) const requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<different-from<basic_const_iterator> I>
constexpr bool operator>=(const I& y) const requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<different-from<basic_const_iterator> I>
constexpr auto operator<=>(const I& y) const requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I> && three_way_comparable_with<Iterator, I>;

friend constexpr basic_const_iterator operator+(const basic_const_iterator& i, difference_type n) requires random_access_iterator<Iterator>;

§ 25.5.3.3
friend constexpr basic_const_iterator operator+(difference_type n, const basic_const_iterator& i) requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n) requires random_access_iterator<Iterator>;

template<sized_sentinel_for<Iterator> S> constexpr difference_type operator-(const S& y) const;
template<not-a-const-iterator S> requires sized_sentinel_for<S, Iterator> friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);
friend constexpr rvalue-reference iter_move(const basic_const_iterator& i) noexcept(noexcept(static_cast<rvalue-reference>(ranges::iter_move(i.current_)))) {
    return static_cast<rvalue-reference>(ranges::iter_move(i.current_));
}

1  Given some type I, the concept not-a-const-iterator is defined as false if I is a specialization of basic_const_iterator and true otherwise.

25.5.3.4 Member types

basic_const_iterator<Iterator>::iterator_concept is defined as follows:

(1.1) — If Iterator models contiguous_iterator, then iterator_concept denotes contiguous_iterator_tag.

(1.2) — Otherwise, if Iterator models random_access_iterator, then iterator_concept denotes random_access_iterator_tag.

(1.3) — Otherwise, if Iterator models bidirectional_iterator, then iterator_concept denotes bidirectional_iterator_tag.

(1.4) — Otherwise, if Iterator models forward_iterator, then iterator_concept denotes forward_iterator_tag.

(1.5) — Otherwise, iterator_concept denotes input_iterator_tag.

2  The member typedef-name iterator_category is defined if and only if Iterator models forward_iterator. In that case, basic_const_iterator<Iterator>::iterator_category denotes the type iterator_traits<Iterator>::iterator_category.

25.5.3.5 Operations

constexpr basic_const_iterator(Iterator current);

Effects: Initializes current_ with std::move(current).

template<convertible_to<Iterator> U> constexpr basic_const_iterator(basic_const_iterator<U> current);

Effects: Initializes current_ with std::move(current_.current_).

template<different-from<basic_const_iterator> T> requires convertible_to<T, Iterator> constexpr basic_const_iterator(T&& current);

Effects: Initializes current_ with std::forward<T>(current).

constexpr const Iterator& base() const & noexcept;

Effects: Equivalent to: return current_;

constexpr Iterator base() &&;

Effects: Equivalent to: return std::move(current_);

constexpr reference operator*() const;

Effects: Equivalent to: return static_cast<reference>(*current_);
constexpr const auto* operator->() const
requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&
same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;

Returns: If Iterator models contiguous_iterator, to_address(current_); otherwise, address-
of(*current_).

constexpr basic_const_iterator& operator++();

Effects: Equivalent to:
++current_; return *this;

constexpr void operator++(int);

Effects: Equivalent to: ++current_;

constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;

Effects: Equivalent to:
auto tmp = *this; +++this; return tmp;

constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;

Effects: Equivalent to:
--current_; return *this;

constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;

Effects: Equivalent to:
auto tmp = *this; --*this; return tmp;

constexpr basic_const_iterator& operator+=(difference_type n) requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n) requires random_access_iterator<Iterator>;

Let op be the operator.

Effects: Equivalent to:
current_ op n; return *this;

constexpr reference operator[](difference_type n) const requires random_access_iterator<Iterator>

Effects: Equivalent to: return static_cast<reference>(current_[n]);

template<sentinel_for<Iterator> S>
constexpr bool operator==(const S& s) const;

Effects: Equivalent to: return current_ == s;

template<not-a-const-iterator CI>
requires constant_iterator<CI> && convertible_to<Iterator const&, CI>
constexpr operator CI() const &;

Returns: current_.

template<not-a-const-iterator CI>
requires constant_iterator<CI> && convertible_to<Iterator, CI>
constexpr operator CI() &;

Returns: std::move(current_).
constexpr bool operator<(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator>(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator<=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator>=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr auto operator<=>(const basic_const_iterator& y) const
requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;

Let \( op \) be the operator.

**Effects:** Equivalent to:
\[
\text{return \ current_} \ op \ y.\text{current}_.;
\]

template<\text{different-from}\text{<basic_const_iterator> }I>
constexpr bool operator<(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr bool operator>(const I& y) const

constexpr bool operator<=(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr bool operator>=(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr auto operator<=>(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I> &&
three_way_comparable_with<Iterator, I>;

Let \( op \) be the operator.

**Effects:** Equivalent to:
\[
\text{return \ current_} \ op \ y;
\]

template<\text{not-a-const-iterator } I>
friend constexpr bool operator<(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator>(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator<=(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator>=(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

Let \( op \) be the operator.

**Effects:** Equivalent to:
\[
\text{return \ x} \ op \ y.\text{current}_.;
\]

friend constexpr basic_const_iterator operator+(const basic_const_iterator& i, difference_type n)
requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator+(difference_type n, const basic_const_iterator& i)
requires random_access_iterator<Iterator>;

**Effects:** Equivalent to:
\[
\text{return basic_const_iterator(i.\text{current}_ + n)};
\]

friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n)
requires random_access_iterator<Iterator>;

**Effects:** Equivalent to:
\[
\text{return basic_const_iterator(i.\text{current}_ - n)};
\]

\text{template<\text{sized_sentinel_for}<\text{Iterator}> S>}
constexpr difference_type operator-(const S& y) const;

**Effects:** Equivalent to:
\[
\text{return \ current}_ - y;
template<not-a-const-iterator S>
requires sized_sentinel_for<S, Iterator>
friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);

Effects: Equivalent to: return x - y.current_;
friend constexpr iter_rvalue_reference_t<Iterator> iter_move(const move_iterator& i) noexcept(noexcept(ranges::iter_move(i.current)));  

private:
  Iterator current;  // exposition only
};

1 The member typedef-name iterator_concept is defined as follows:

(1.1) — If Iterator models random_access_iterator, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if Iterator models bidirectional_iterator, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, if Iterator models forward_iterator, then iterator_concept denotes forward_iterator_tag.
(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member typedef-name iterator_category is defined if and only if the qualified-id iterator_traits<Iterator>::iterator_category is valid and denotes a type. In that case, iterator_category denotes

(2.1) — random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models derived_from<random_access_iterator_tag>, and
(2.2) — iterator_traits<Iterator>::iterator_category otherwise.

25.5.4.3 Requirements

1 The template parameter Iterator shall either meet the Cpp17InputIterator requirements (25.3.5.3) or model input_iterator (25.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the Cpp17BidirectionalIterator requirements (25.3.5.6) or model bidirectional_iterator (25.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the Cpp17RandomAccessIterator requirements (25.3.5.7) or model random_access_iterator (25.3.4.13).

25.5.4.4 Construction and assignment

constexpr move_iterator();

1 Effects: Value-initializes current.

constexpr explicit move_iterator(Iterator i);

2 Effects: Initializes current with std::move(i).

template<class U> constexpr move_iterator(const move_iterator<U>& u);

3 Constraints: is_same_v<U, Iterator> is false and const U& models convertible_to<Iterator>.

4 Effects: Initializes current with u.current.

template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

5 Constraints: is_same_v<U, Iterator> is false, const U& models convertible_to<Iterator>, and assignable_from<Iterator&, const U&> is modeled.

6 Effects: Assigns u.current to current.

7 Returns: *this.

25.5.4.5 Conversion

constexpr const Iterator& base() const & noexcept;

1 Returns: current.
constexpr Iterator base() &&;

Returns: std::move(current).

25.5.4.6 Element access

constexpr reference operator*() const;

Effects: Equivalent to: return ranges::iter_move(current);

constexpr reference operator[](difference_type n) const;

Effects: Equivalent to: return ranges::iter_move(current + n);

25.5.4.7 Navigation

constexpr move_iterator& operator++();

Effects: As if by ++current.

Returns: *this.

constexpr auto operator++(int);

Effects: If Iterator models forward_iterator, equivalent to:

move_iterator tmp = *this;
++current;
return tmp;

Otherwise, equivalent to ++current.

constexpr move_iterator& operator--();

Effects: As if by --current.

Returns: *this.

constexpr move_iterator operator--(int);

Effects: As if by:

move_iterator tmp = *this;
--current;
return tmp;

constexpr move_iterator operator+(difference_type n) const;

Returns: move_iterator(current + n).

constexpr move_iterator& operator+=(difference_type n);

Effects: As if by:

current += n;

Returns: *this.

constexpr move_iterator operator-(difference_type n) const;

Returns: move_iterator(current - n).

constexpr move_iterator& operator-=(difference_type n);

Effects: As if by: current -= n;

Returns: *this.

25.5.4.8 Comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const move_iterator<Iterator1>& x,
const move_iterator<Iterator2>& y);

template<sentinel_for<Iterator> S>
friend constexpr bool operator==(const move_iterator& x,
const move_sentinel<S>& y);

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().

§ 25.5.4.8
template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: !(y < x).

template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: y < x.

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: !(x < y).

template<class Iterator1, class Iterator2>
constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: x.base() <=> y.base().

25.5.4.9 Non-member functions

template<class Iterator1, class Iterator2>
constexpr auto operator-=
(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());

template<sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_sentinel<S>& x, const move_iterator& y);

Returns: x.base() - y.base().

template<class Iterator>
constexpr move_iterator<Iterator>
operator+(iter_difference_t<Iterator> n, const move_iterator<Iterator>& x);

Constraints: x.base() + n is well-formed and has type Iterator.
Returns: x + n.

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)));

Effects: Equivalent to: return ranges::iter_move(i.current);

template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

Effects: Equivalent to: ranges::iter_swap(x.current, y.current).
template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

Returns: move_iterator<Iterator>(std::move(i)).

25.5.4.10 Class template move_sentinel

Class template move_sentinel is a sentinel adaptor useful for denoting ranges together with move_iterator. When an input iterator type I and sentinel type S model sentinel_for<S, I>, move_sentinel<S> and move_iterator<I> model sentinel_for<move_sentinel<S>, move_iterator<I>> as well.

[Example 1: A move_if algorithm is easily implemented with copy_if using move_iterator and move_sentinel:

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, indirect_unary_predicate<I> Pred>
requires indirectly_movable<I, O>
void move_if(I first, S last, O out, Pred pred) {
  ranges::copy_if(move_iterator<I>{std::move(first)}, move_sentinel<S>{last}, std::move(out), pred);
}
—end example]

namespace std {
  template<semiregular S>
  class move_sentinel {
    public:
      constexpr move_sentinel();
      constexpr explicit move_sentinel(S s);
      template<class S2>
      requires convertible_to<const S2&, S>
      constexpr move_sentinel(const move_sentinel<S2>& s);
      template<class S2>
      requires assignable_from<S&, const S2&>
      constexpr move_sentinel& operator=(const move_sentinel<S2>& s);
    
      constexpr S base() const;
    
    private:
      S last;  // exposition only
  };
}

25.5.4.11 Operations

constexpr move_sentinel();

Effects: Value-initializes last. If is_trivially_default_constructible_v<S> is true, then this constructor is a constexpr constructor.

constexpr explicit move_sentinel(S s);

Effects: Initializes last with std::move(s).

template<class S2>
requires convertible_to<const S2&, S>
constexpr move_sentinel(const move_sentinel<S2>& s);

Effects: Initializes last with s.last.

template<class S2>
requires assignable_from<S&, const S2&>
constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

Effects: Equivalent to: last = s.last; return *this;

constexpr S base() const;

Returns: last.
25.5.5 Common iterators

25.5.5.1 Class template common_iterator

Class template common_iterator is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

[Note 1: The common_iterator type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type. — end note]

[Example 1:

```cpp
template<class ForwardIterator>
void fun(ForwardIterator begin, ForwardIterator end);

list<int> s;
// populate the list s
using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
// call fun on a range of 10 ints
fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel));
```

—end example]

namespace std {
    template<input_or_output_iterator I, sentinel_for<I> S>
    requires (!same_as<I, S> && copyable<I>)
    class common_iterator {
    public:
        constexpr common_iterator() requires default_initializable<I> = default;
        constexpr common_iterator(I i);
        constexpr common_iterator(S s);
        template<class I2, class S2>
        requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
        constexpr common_iterator(const common_iterator<I2, S2>& x);
        template<class I2, class S2>
        requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
        && assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
        constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);
        constexpr decltype(auto) operator*();
        constexpr decltype(auto) operator*() const requires dereferenceable<const I>;
        constexpr auto operator->() const requires see below;
        constexpr common_iterator& operator++();
        constexpr decltype(auto) operator++(int);
        template<class I2, sentinel_for<I> S2>
        requires sentinel_for<S, I2>
        friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
        template<class I2, sentinel_for<I> S2>
        requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
        friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
        template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
        requires sized_sentinel_for<S, I2>
        friend constexpr iter_difference_t<I2> operator-(
            const common_iterator& x, const common_iterator<I2, S2>& y);
        friend constexpr decltype(auto) iter_move(const common_iterator& i)
        noexcept(noexcept(ranges::iter_move(declval<const I&>())))
        requires input_iterator<I>;
```
template<indirectly_swappable<I> I2, class S2>
friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
    noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>()));

private:
    variant<I, S> v_; // exposition only
};

template<class I, class S>
struct incrementable_traits<common_iterator<I, S>>
{
    using difference_type = iter_difference_t<I>;
};

template<input_iterator I, class S>
struct iterator_traits<common_iterator<I, S>>
{
    using iterator_concept = see below; // not always present
    using iterator_category = see below;
    using value_type = iter_value_t<I>;
    using difference_type = iter_difference_t<I>;
    using pointer = see below;
    using reference = iter_reference_t<I>;
};

25.5.5.2 Associated types

1. The nested typedef-name iterator_category of the specialization of iterator_traits for common_iterator<I, S> is defined if and only if iter_difference_t<I> is an integral type. In that case, iterator_category denotes forward_iterator_tag if the qualified-id iterator_traits<I>::iterator_category is valid and denotes a type that models derived_from<forward_iterator_tag>; otherwise it denotes input_iterator_tag.

2. The remaining nested typedef-names of the specialization of iterator_traits for common_iterator<I, S> are defined as follows:

   (2.1) — iterator_concept denotes forward_iterator_tag if I models forward_iterator; otherwise it denotes input_iterator_tag.

   (2.2) — Let a denote an lvalue of type const common_iterator<I, S>. If the expression a.operator->() is well-formed, then pointer denotes decltype(a.operator->()). Otherwise, pointer denotes void.

25.5.5.3 Constructors and conversions

constexpr common_iterator(I i);

1. Effects: Initializes v_ as if by v_{in_place_type<I>, std::move(i)}.

consexpr common_iterator(S s);

2. Effects: Initializes v_ as if by v_{in_place_type<S>, std::move(s)}.

template<class I2, class S2>
requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
constexpr common_iterator(const common_iterator<I2, S2>& x);

3. Preconditions: x.v_.valueless_by_exception() is false.

4. Effects: Initializes v_ as if by v_{in_place_index<i>, get<i>(x.v_)}, where i is x.v_.index().

template<class I2, class S2>
requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
    assignable_from<I&, const I2&>, assignable_from<S&, const S2&>
constexpr common_iterator(const common_iterator<I2, S2>& x);

5. Preconditions: x.v_.valueless_by_exception() is false.

6. Effects: Equivalent to:

   (6.1) — If v_.index() == x.v_.index(), then get<i>(v_) = get<i>(x.v_).

   (6.2) — Otherwise, v_.emplace<i>(get<i>(x.v_)).
where \( i \) is \( \text{x.v_.index()} \).

\[ \text{Returns: } *\text{this}. \]

### 25.5.5.4 Accessors

```cpp
constexpr decltype(auto) operator*();
```

- **Preconditions:** holds_alternative<\( I \)>(v_) is true.
- **Effects:** Equivalent to: return *get<\( I \)>(v_);

```cpp
constexpr decltype(auto) operator*() const
requires dereferenceable<\( \text{const } I \)>
```

- **Preconditions:** holds_alternative<\( I \)>(v_) is true.
- **Effects:** Equivalent to: return *get<\( I \)>(v_);

### 25.5.5.5 Navigation

```cpp
constexpr common_iterator& operator++();
```

- **Preconditions:** holds_alternative<\( I \)>(v_) is true.
- **Effects:** Equivalent to ++get<\( I \)>(v_);

```cpp
constexpr decltype(auto) operator++(int);
```

- **Preconditions:** holds_alternative<\( I \)>(v_) is true.
- **Effects:** If \( I \) models forward_iterator, equivalent to:
  ```cpp
template <false_type>
  common_iterator tmp = *this;
  ++tmp;
  return tmp;
```
  Otherwise, if requires(I& i) { { *i++ } -> can-reference; } is true or
  ```cpp
  indirectly_readable<\( I \) & & constructible_from<iter_value_t<\( I \)>, iter_reference_t<\( I \)>& & move_constructible<iter_value_t<\( I \)>>&
  ```
  is false, equivalent to:
  ```cpp
  return get<\( I \)>(v_++);
  ```

§ 25.5.5.5 1139
Otherwise, equivalent to:

```cpp
postfix-proxy p(**this);
++*this;
return p;
```

where `postfix-proxy` is the exposition-only class:

```cpp
class postfix-proxy {
  iter_value_t<I> keep_;
  constexpr postfix-proxy(iter_reference_t<I>&& x)
    : keep_(std::forward<iter_reference_t<I>>(x)) {}  
public:
  constexpr const iter_value_t<I>& operator*() const noexcept {
    return keep_;  
  }
};
```

### 25.5.5.6 Comparisons [common.iter.cmp]

```cpp
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2>
friend constexpr bool operator==(  
  const common_iterator& x,  
  const common_iterator<I2, S2>& y);
```

1. **Preconditions:** `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
2. **Returns:** true if `i == j`, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

```cpp
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
friend constexpr bool operator==(  
  const common_iterator& x,  
  const common_iterator<I2, S2>& y);
```

3. **Preconditions:** `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
4. **Returns:** true if `i` and `j` are each 1, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

```cpp
template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
requires sized_sentinel_for<S, I2>
friend constexpr iter_difference_t<I2> operator-(  
  const common_iterator& x,  
  const common_iterator<I2, S2>& y);
```

5. **Preconditions:** `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
6. **Returns:** 0 if `i` and `j` are each 1, and otherwise `get<i>(x.v_) - get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

### 25.5.5.7 Customizations [common.iter.cust]

```cpp
friend constexpr decltype(auto) iter_move(const common_iterator& i)
  noexcept(noexcept(ranges::iter_move(declval<const I&>())))
  requires input_iterator<I>;
```

1. **Preconditions:** `holds_alternative<I>(i.v_)` is true.
2. **Effects:** Equivalent to: `return ranges::iter_move(get<I>(i.v_));`

```cpp
template<indirectly_swappable<I> I2, class S2>
friend constexpr void iter_swap(const common_iterator& x,  
  const common_iterator<I2, S2>& y)
  noexcept(noexcept(ranges::iter_swap(declval<const I&>()),  
  declval<const I2&>()));
```

3. **Preconditions:** `holds_alternative<I>(x.v_)` and `holds_alternative<I2>(y.v_)` are each true.
4. **Effects:** Equivalent to `ranges::iter_swap(get<I>(x.v_), get<I2>(y.v_));`

§ 25.5.5.7
25.5.6 Default sentinel [default.sentinel]

namespace std {
  struct default_sentinel_t { };
}

1 Class `default_sentinel_t` is an empty type used to denote the end of a range. It can be used together with iterator types that know the bound of their range (e.g., `counted_iterator` (25.5.7.1)).

25.5.7 Counted iterators [iterators.counted]

25.5.7.1 Class template `counted_iterator` [counted.iterator]

1 Class template `counted_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that it keeps track of the distance to the end of its range. It can be used together with `default_sentinel` in calls to generic algorithms to operate on a range of N elements starting at a given position without needing to know the end position a priori.

2 [Example 1:]

```cpp
list<string> s;
// populate the list s with at least 10 strings
vector<string> v;
// copies 10 strings into v:
ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
```

—end example]

3 Two values `i1` and `i2` of types `counted_iterator<I1>` and `counted_iterator<I2>` refer to elements of the same sequence if and only if there exists some integer n such that `next(i1.base(), i1.count() + n)` and `next(i2.base(), i2.count() + n)` refer to the same (possibly past-the-end) element.

```cpp
namespace std {
  template<input_or_output_iterator I>
  class counted_iterator {
    public:
      using iterator_type = I;
      using value_type = iter_value_t<I>;
      // present only
      // if I models indirectly_readable
      using difference_type = iter_difference_t<I>;
      using iterator_concept = typename I::iterator_concept;
      // present only
      // if the qualified-id I::iterator_concept is valid and denotes a type
      using iterator_category = typename I::iterator_category;
      // present only
      // if the qualified-id I::iterator_category is valid and denotes a type
      constexpr counted_iterator() requires default_initializable<I> = default;
      constexpr counted_iterator(I x, iter_difference_t<I> n);
      template<class I2>
      requires convertible_to<const I2&, I>
      constexpr counted_iterator(const counted_iterator<I2>& x);
      template<class I2>
      requires assignable_from<I&, const I2&>
      constexpr counted_iterator& operator=(const counted_iterator<I2>& x);
      constexpr const I& base() const & noexcept;
      constexpr I base() &&;
      constexpr iter_difference_t<I> count() const noexcept;
      constexpr decltype(auto) operator*();
      constexpr decltype(auto) operator*() const
          requires dereferenceable<const I>;
      constexpr auto operator->() const noexcept
          requires contiguous_iterator<I>;
      constexpr counted_iterator& operator++();
      constexpr decltype(auto) operator++(int);
      constexpr counted_iterator operator++(int)
          requires forward_iterator<I>;
  }
}
```

§ 25.5.7.1 1141
constexpr counted_iterator& operator--()  
requires bidirectional_iterator<I>;
constexpr counted_iterator operator--(int)  
requires bidirectional_iterator<I>;

constexpr counted_iterator operator+(iter_difference_t<I> n) const  
requires random_access_iterator<I>;
friend constexpr counted_iterator operator+(  
    iter_difference_t<I> n, const counted_iterator& x)  
requires random_access_iterator<I>;
constexpr counted_iterator& operator+=(iter_difference_t<I> n)  
requires random_access_iterator<I>;

constexpr counted_iterator operator-(iter_difference_t<I> n) const  
requires random_access_iterator<I>;
template<common_with<I> I2>  
friend constexpr iter_difference_t<I2> operator-(  
    const counted_iterator& x, const counted_iterator<I2>& y);

    const counted_iterator& x, default_sentinel_t);
friend constexpr iter_difference_t<I> operator-(  
    default_sentinel_t, const counted_iterator& y);
constexpr counted_iterator& operator-=(iter_difference_t<I> n)  
requires random_access_iterator<I>;

constexpr decltype(auto) operator[](iter_difference_t<I> n) const  
requires random_access_iterator<I>;
template<common_with<I> I2>  
friend constexpr bool operator==(const counted_iterator& x, const counted_iterator<I2>& y)  
requires input_iterator<I>;

private:
    I current = I();  // exposition only
    iter_difference_t<I> length = 0;  // exposition only

};

template<input_iterator I>  
requires same_as<ITER_TRAITS(I), iterator_traits<I>>  // see 25.3.4.1
struct iterator_traits<counted_iterator<I>> : iterator_traits<I> {  
    using pointer = conditional_t<contiguous_iterator<I>,  
        add_pointer_t<iter_reference_t<I>>, void>;
};

25.5.7.2 Constructors and conversions

constexpr counted_iterator(I i, iter_difference_t<I> n);  

1 Preconditions: n >= 0.
2 Effects: Initializes current with std::move(i) and length with n.
template<class I2>
  requires convertible_to< const I2&, I>
  constexpr counted_iterator(const counted_iterator<I2>& x);

  Effects: Initializes current with x.current and length with x.length.

template<class I2>
  requires assignable_from<I&, const I2&>
  constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

  Effects: Assigns x.current to current and x.length to length.
  Returns: *this.

25.5.7.3 Accessors

constexpr const I& base() const & noexcept;
  Effects: Equivalent to: return current;

constexpr I base() &&;
  Returns: std::move(current).

constexpr iter_difference_t<I> count() const noexcept;
  Effects: Equivalent to: return length;

25.5.7.4 Element access

constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const requires dereferenceable<const I>;
  Preconditions: length > 0 is true.
  Effects: Equivalent to: return *current;

constexpr auto operator->() const noexcept requires contiguous_iterator<I>;
  Effects: Equivalent to: return to_address(current);

constexpr decltype(auto) operator[](iter_difference_t<I> n) const requires random_access_iterator<I>;
  Preconditions: n < length.
  Effects: Equivalent to: return current[n];

25.5.7.5 Navigation

constexpr counted_iterator& operator++();
  Preconditions: length > 0.
  Effects: Equivalent to:
        ++current;
        --length;
        return *this;

constexpr decltype(auto) operator++(int);
  Preconditions: length > 0.
  Effects: Equivalent to:
        --length;
        try { return current++; } 
        catch(...) { ++length; throw; }

constexpr counted_iterator operator++(int) requires forward_iterator<I>;
  Effects: Equivalent to:
counted_iterator tmp = *this;
+++this;
return tmp;

constexpr counted_iterator& operator--() 
requires bidirectional_iterator<I>;

Effects: Equivalent to:

requires random_access_iterator<I>;

Effects: Equivalent to: return x + n;

constexpr counted_iterator& operator+=(iter_difference_t<I> n) 
requires random_access_iterator<I>;

Preconditions: n <= length.

Effects: Equivalent to:
  current += n;
  length -= n;
  return *this;

constexpr counted_iterator operator-(iter_difference_t<I> n) const 
requires random_access_iterator<I>;

Effects: Equivalent to: return counted_iterator(current - n, length + n);

template<common_with<I> I2>
friend constexpr iter_difference_t<I2> operator-( 
  const counted_iterator& x, const counted_iterator<I2>& y);

Preconditions: x and y refer to elements of the same sequence (25.5.7.1).

Effects: Equivalent to: return y.length - x.length;

friend constexpr iter_difference_t<I> operator-( 
  const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return -x.length;

friend constexpr iter_difference_t<I> operator-( 
  default_sentinel_t, const counted_iterator& y);

Effects: Equivalent to: return y.length;

constexpr counted_iterator& operator-=(iter_difference_t<I> n) 
requires random_access_iterator<I>;

Preconditions: -n <= length.

Effects: Equivalent to:
  current -= n;

§ 25.5.7.5
length += n;
return *this;

25.5.7.6 Comparisons

template<common_with<I> I2>
friend constexpr bool operator==(const counted_iterator& x, const counted_iterator<I2>& y);

1 Preconditions: x and y refer to elements of the same sequence (25.5.7.1).
2 Effects: Equivalent to: return x.length == y.length;

friend constexpr bool operator==(const counted_iterator& x, default_sentinel_t);
3 Effects: Equivalent to: return x.length == 0;

template<common_with<I> I2>
friend constexpr strong_ordering operator<=>(const counted_iterator& x, const counted_iterator<I2>& y);

4 Preconditions: x and y refer to elements of the same sequence (25.5.7.1).
5 Effects: Equivalent to: return y.length <=> x.length;
6 [Note 1: The argument order in the Effects: element is reversed because length counts down, not up. — end note]

25.5.7.7 Customizations

friend constexpr decltype(auto) iter_move(const counted_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)))
requires input_iterator<I>;

1 Preconditions: i.length > 0 is true.
2 Effects: Equivalent to: return ranges::iter_move(i.current);

template<indirectly_swappable<I> I2>
friend constexpr void iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

3 Preconditions: Both x.length > 0 and y.length > 0 are true.
4 Effects: Equivalent to ranges::iter_swap(x.current, y.current).

25.5.8 Unreachable sentinel

Class unreachable_sentinel_t can be used with any weakly_incrementable type to denote the “upper bound” of an unbounded interval.

1 [Example 1:

```
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel_t, 'n');
```

Provided a newline character really exists in the buffer, the use of unreachable_sentinel above potentially makes the call to find more efficient since the loop test against the sentinel does not require a conditional branch. — end example]

namespace std {
struct unreachable_sentinel_t {
  template<weakly_incrementable I>
  friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept
  { return false; }
};
}
25.6 Stream iterators

25.6.1 General

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example 1:
  partial_sum(istream_iterator<double, char>(cin),
              istream_iterator<double, char>(),
              ostream_iterator<double, char>(cout, "\n"));
  reads a file containing floating-point numbers from cin, and prints the partial sums onto cout. — end example]

25.6.2 Class template `istream_iterator`

25.6.2.1 General

The class template `istream_iterator` is an input iterator (25.3.5.3) that reads successive elements from the input stream for which it was constructed.

```
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>,
             class Distance = ptrdiff_t>
    class istream_iterator {
      public:
        using iterator_category = input_iterator_tag;
        using value_type = T;
        using difference_type = Distance;
        using pointer = const T*;
        using reference = const T&;
        using char_type = charT;
        using traits_type = traits;
        using istream_type = basic_istream<charT, traits>;
        constexpr istream_iterator();
        constexpr istream_iterator(default_sentinel_t);
        istream_iterator(istream_type& s);
        constexpr istream_iterator(const istream_iterator& x) noexcept(see below);
        ~istream_iterator() = default;
        istream_iterator& operator=(const istream_iterator&);  // all conversions

        const T& operator*() const;
        const T* operator->() const;
        istream_iterator& operator++();
        istream_iterator operator++(int);

        friend bool operator==(const istream_iterator& i, default_sentinel_t);
      private:
        basic_istream<charT, traits>* in_stream;  // exposition only
        T value;  // exposition only
    };
}
```

2 The type `T` shall meet the Cpp17DefaultConstructible, Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.

25.6.2.2 Constructors and destructor

```
constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);

Effects: Constructs the end-of-stream iterator, value-initializing value.

Postconditions: in_stream == nullptr is true.

Remarks: If the initializer `T()` in the declaration `auto x = T();` is a constant initializer (7.7), then these constructors are constexpr constructors.
```
`istream_iterator(istream_type& s);`

**Effects:** Initializes `in_stream` with `addressof(s)`, value-initializes `value`, and then calls `operator++()`.

`constexpr istream_iterator(const istream_iterator& x) noexcept(see below);`

**Effects:** Initializes `in_stream` with `x.in_stream` and initializes `value` with `x.value`.

**Remarks:** An invocation of this constructor may be used in a core constant expression if and only if the initialization of `value` from `x.value` is a constant subexpression (3.14). The exception specification is equivalent to `is_nothrow_copy_constructible_v<T>`.

`~istream_iterator() = default;`

**Remarks:** If `is_trivially_destructible_v<T>` is true, then this destructor is trivial.

### 25.6.2.3 Operations

#### [istream.iterator.ops]

`const T& operator*() const;`

**Preconditions:** `in_stream != nullptr` is true.

**Returns:** `value`.

`const T* operator->() const;`

**Preconditions:** `in_stream != nullptr` is true.

**Returns:** `addressof(value)`.

`istream_iterator& operator++();`

**Preconditions:** `in_stream != nullptr` is true.

**Effects:** Equivalent to:

```
if (!(*in_stream >> value))
    in_stream = nullptr;
```

**Returns:** `*this`.

`istream_iterator operator++(int);`

**Preconditions:** `in_stream != nullptr` is true.

**Effects:** Equivalent to:

```
istream_iterator tmp = *this;
++*this;
return tmp;
```

`template<class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
const istream_iterator<T,charT,traits,Distance>& y);`

**Returns:** `x.in_stream == y.in_stream`.

`friend bool operator==(const istream_iterator& i, default_sentinel_t);`

**Returns:** `!i.in_stream`.

### 25.6.3 Class template ostream_iterator

#### [ostream.iterator]

#### 25.6.3.1 General

#### [ostream.iterator.general]

`ostream_iterator` writes (using `operator<<`) successive elements onto the output stream from which it was constructed. If it was constructed with `charT*` as a constructor argument, this string, called a delimiter string, is written to the stream after every `T` is written.

```cpp
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>>
    class ostream_iterator {
        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
    }
```
using pointer = void;
using reference = void;
using char_type = charT;
using traits_type = traits;
using ostream_type = basic_ostream<charT,traits>;

ostream_iterator(ostream_type& s);
ostream_iterator(ostream_type& s, const charT* delimiter);

~ostream_iterator();
ostream_iterator& operator=(const ostream_iterator&);  
ostream_iterator& operator=(const T& value);
ostream_iterator& operator*();
ostream_iterator& operator++();
ostream_iterator& operator++(int);

private:
    basic_ostream<charT,traits>* out_stream;                           // exposition only
    const charT* delim;                                               // exposition only
};

25.6.3.2 Constructors and destructor

ostream_iterator(ostream_type& s);
Effects: Initializes out_stream with addressof(s) and delim with nullptr.

ostream_iterator(ostream_type& s, const charT* delimiter);
Effects: Initializes out_stream with addressof(s) and delim with delimiter.

25.6.3.3 Operations

ostream_iterator& operator=(const T& value);
Effects: As if by:
    *out_stream << value;
    if (delim)
        *out_stream << delim;
    return *this;

ostream_iterator& operator*();
Returns: *this.

ostream_iterator& operator++();
ostream_iterator& operator++(int);
Returns: *this.

25.6.4 Class template istreambuf_iterator

25.6.4.1 General

The class template istreambuf_iterator defines an input iterator (25.3.5.3) that reads successive characters from the streambuf for which it was constructed. operator* provides access to the current input character, if any. Each time operator++ is evaluated, the iterator advances to the next input character. If the end of stream is reached (streambuf_type::sgetc() returns traits::eof()), the iterator becomes equal to the end-of-stream iterator value. The default constructor istreambuf_iterator() and the constructor istreambuf_iterator(nullptr) both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of istreambuf_iterator shall have a trivial copy constructor, a constexpr default constructor, and a trivial destructor.

The result of operator*() on an end-of-stream iterator is undefined. For any other iterator value a char_type value is returned. It is impossible to assign a character via an input iterator.
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
public:
    using iterator_category = input_iterator_tag;
    using value_type = charT;
    using difference_type = typename traits::off_type;
    using pointer = unspecified;
    using reference = charT;
    using char_type = charT;
    using traits_type = traits;
    using int_type = typename traits::int_type;
    using streambuf_type = basic_streambuf<charT,traits>;
    using istream_type = basic_istream<charT,traits>;

    class proxy;

    constexpr istreambuf_iterator() noexcept; // exposition only
    constexpr istreambuf_iterator(default_sentinel_t) noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
    ~istreambuf_iterator() = default;
    istreambuf_iterator(istream_type& s) noexcept;
    istreambuf_iterator(streambuf_type* s) noexcept;
    istreambuf_iterator(const proxy& p) noexcept;
    istreambuf_iterator& operator=(const istreambuf_iterator&) noexcept = default;
    charT operator*() const;
    istreambuf_iterator& operator++();
    proxy operator++(int);
    bool equal(const istreambuf_iterator& b) const;

    friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

private:
    streambuf_type* sbuf_; // exposition only
};

25.6.4.2 Class istreambuf_iterator::proxy

Class istreambuf_iterator<charT,traits>::proxy is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class istreambuf_iterator<charT,traits>::proxy provides a temporary placeholder as the return value of the post-increment operator (operator++). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

namespace std {
    template<class charT, class traits>
    class istreambuf_iterator<charT, traits>::proxy { // exposition only
        charT keep_;
        basic_streambuf<charT,traits>* sbuf_;
        proxy(charT c, basic_streambuf<charT,traits>* sbuf) : keep_(c), sbuf_(sbuf) { }
    public:
        charT operator*() { return keep_; }
    }
};

25.6.4.3 Constructors

For each istreambuf_iterator constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member sbuf_ is initialized with a null pointer value.

constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;

Effects: Initializes sbuf_ with nullptr.

istreambuf_iterator(istream_type& s) noexcept;

Effects: Initializes sbuf_ with s.rdbuf().

istreambuf_iterator(streambuf_type* s) noexcept;

Effects: Initializes sbuf_ with s.

istreambuf_iterator(const proxy& p) noexcept;

Effects: Initializes sbuf_ with p.sbuf_.

25.6.4.4 Operations [istreambuf.iterator.ops]

charT operator*() const;

Returns: The character obtained via the streambuf member sbuf_->sgetc().

istreambuf_iterator& operator++();

Effects: As if by sbuf_->sbumpc().

Returns: *this.

proxy operator++(int);

Returns: proxy(sbuf_->sbumpc(), sbuf_).

bool equal(const istreambuf_iterator& b) const;

Returns: true if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what streambuf object they use.

template<class charT, class traits>
bool operator==(const istreambuf_iterator<charT, traits>& a,
const istreambuf_iterator<charT, traits>& b);

Returns: a.equal(b).

friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

Returns: i.equal(s).

25.6.5 Class template ostreambuf_iterator [ostreambuf.iterator]

25.6.5.1 General [ostreambuf.iterator.general]

The class template ostreambuf_iterator writes successive characters onto the output stream from which it was constructed.

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class ostreambuf_iterator {
        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using char_type = charT;
            using traits_type = traits;
            using streambuf_type = basic_streambuf<charT, traits>;
            using ostream_type = basic_ostream<charT, traits>;

            ostreambuf_iterator(ostream_type& s) noexcept;
            ostreambuf_iterator(streambuf_type* s) noexcept;
            ostreambuf_iterator& operator=(charT c);

        } // class ostreambuf_iterator
    } // template ostreambuf_iterator
} // namespace std
25.6.5.2 Constructors

ostreambuf_iterator(ostream_type& s) noexcept;

1 Preconditions: s.rdbuf() is not a null pointer.
2 Effects: Initializes sbuf_ with s.rdbuf().

ostreambuf_iterator(streambuf_type* s) noexcept;

3 Preconditions: s is not a null pointer.
4 Effects: Initializes sbuf_ with s.

25.6.5.3 Operations

ostreambuf_iterator& operator=(charT c);

1 Effects: If failed() yields false, calls sbuf_->sputc(c); otherwise has no effect.
2 Returns: *this.

ostreambuf_iterator& operator*();
3 Returns: *this.

ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
4 Returns: *this.

bool failed() const noexcept;
5 Returns: true if in any prior use of member operator=, the call to sbuf_->sputc() returned traits::eof(); or false otherwise.

25.7 Range access

In addition to being available via inclusion of the <iterator> header, the function templates in 25.7 are available when any of the following headers are included: <array> (24.3.2), <deque> (24.3.3), <flat_map> (24.6.4), <flat_set> (24.6.5), <forward_list> (24.3.4), <list> (24.3.5), <map> (24.4.2), <regex> (32.3), <set> (24.4.3), <span> (24.7.2.1), <string> (23.4.2), <string_view> (23.3.2), <unordered_map> (24.5.2), <unordered_set> (24.5.3), and <vector> (24.3.6).

template<class C> constexpr auto begin(C& c) -> decltype(c.begin());
template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());
2 Returns: c.begin().

template<class C> constexpr auto end(C& c) -> decltype(c.end());
template<class C> constexpr auto end(const C& c) -> decltype(c.end());
3 Returns: c.end().

template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
4 Returns: array.

template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
5 Returns: array + N.
template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
    -> decltype(std::begin(c));

Returns: std::begin(c).

template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
    -> decltype(std::end(c));

Returns: std::end(c).

template<class C> constexpr auto rbeg(C c) -> decltype(c.rbegin());
template<class C> constexpr auto rbeg(const C& c) -> decltype(c.rbegin());

Returns: c.rbegin().

template<class C> constexpr auto rend(C c) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());

Returns: c.rend().

template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);

Returns: reverse_iterator<T*>(array + N).

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);

Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));

Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));

Returns: std::rend(c).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());

Returns: c.size().

template<class C> [[nodiscard]] constexpr auto empty(const C& c) -> decltype(c.empty());

Returns: c.empty().

template<class T, size_t N> [[nodiscard]] constexpr bool empty(const T (&array)[N]) noexcept;

Returns: false.

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;

Returns: il.size() == 0.

template<class C> constexpr auto data(C c) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) -> decltype(c.data());

Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;

Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;

Returns: il.begin().
26 Ranges library

26.1 General

This Clause describes components for dealing with ranges of elements.

The following subclauses describe range and view requirements, and components for range primitives and range generators as summarized in Table 92.

Table 92 — Ranges library summary

<table>

        // freestanding
    }

1 Within this Clause, for an integer-like type \(X\) (25.3.4.4), \(\text{make-unsigned-like-t}<X>\) denotes \(\text{make_unsigned-t}<X>\) if \(X\) is an integer type; otherwise, it denotes a corresponding unspecified unsigned-integer-like type of the same width as \(X\). For an expression \(x\) of type \(X\), \(\text{to-unsigned-like}(x)\) is \(x\) explicitly converted to \(\text{make-unsigned-like-t}<X>\).
Also within this Clause, `make-signed-like-t<X>` for an integer-like type `X` denotes `make_signed_t<X>` if `X` is an integer type; otherwise, it denotes a corresponding unspecified signed-integer-like type of the same width as `X`.

26.3 Range access

26.3.1 General

In addition to being available via inclusion of the `<ranges>` header, the customization point objects in 26.3 are available when the header `<iterator>` (25.2) is included.

2 Within 26.3, the reified object of a subexpression `E` denotes

(2.1) — the same object as `E` if `E` is a glvalue, or
(2.2) — the result of applying the temporary materialization conversion (7.3.5) to `E` otherwise.

26.3.2 `ranges::begin`

The name `ranges::begin` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::begin(E)` is ill-formed.
(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::begin(E)` is ill-formed with no diagnostic required.
(2.3) — Otherwise, if `T` is an array type, `ranges::begin(E)` is expression-equivalent to `t + 0`.
(2.4) — Otherwise, if `auto(t.begin())` is a valid expression whose type models `input_or_output_iterator`, `ranges::begin(E)` is expression-equivalent to `auto(t.begin())`.
(2.5) — Otherwise, if `T` is a class or enumeration type and `auto(begin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `begin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::begin(E)` is expression-equivalent to that expression.
(2.6) — Otherwise, `ranges::begin(E)` is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::begin(E)` appears in the immediate context of a template instantiation. — end note]

4 [Note 2: Whenever `ranges::begin(E)` is a valid expression, its type models `input_or_output_iterator`. — end note]

26.3.3 `ranges::end`

The name `ranges::end` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

(2.1) — If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::end(E)` is ill-formed.
(2.2) — Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::end(E)` is ill-formed with no diagnostic required.
(2.3) — Otherwise, if `t` is an array of unknown bound, `ranges::end(E)` is ill-formed.
(2.4) — Otherwise, if `auto(t.end())` is a valid expression whose type models `sentinel_for<iterator_t<T>>` then `ranges::end(E)` is expression-equivalent to `auto(t.end())`.
(2.5) — Otherwise, if `auto(t.end())` is a valid expression whose type models `sentinel_for<iterator_t<T>>` where the meaning of `end` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::end(E)` is expression-equivalent to that expression.
(2.6) — Otherwise, `ranges::end(E)` is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::end(E)` appears in the immediate context of a template instantiation. — end note]

4 [Note 2: Whenever `ranges::end(E)` is a valid expression, the types `S` and `I` of `ranges::end(E)` and `ranges::begin(E)` model `sentinel_for<S, I>`. — end note]
26.3.4 ranges::cbegin

The name ranges::cbegin denotes a customization point object (16.3.3.3.5). Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and \( \text{enable\_borrowed\_range<remove\_cv\_t<T>}> \) is false, ranges::cbegin(\( E \)) is ill-formed.
2. Otherwise, let \( U \) be ranges::begin(\( \text{possibly\_const\_range\_t}(t) \)). ranges::cbegin(\( E \)) is expression-equivalent to \( \text{const\_iterator<decltype(U)>}(U) \).

[Note 1: Whenever ranges::cbegin(\( E \)) is a valid expression, its type models \text{input\_or\_output\_iterator} and \text{constant\_iterator}. — end note]

26.3.5 ranges::cend

The name ranges::cend denotes a customization point object (16.3.3.3.5). Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and \( \text{enable\_borrowed\_range<remove\_cv\_t<T>}> \) is false, ranges::cend(\( E \)) is ill-formed.
2. Otherwise, let \( U \) be ranges::end(\( \text{possibly\_const\_range\_t}(t) \)). ranges::cend(\( E \)) is expression-equivalent to \( \text{const\_sentinel<decltype(U)>}(U) \).

[Note 1: Whenever ranges::cend(\( E \)) is a valid expression, the types \( S \) and \( I \) of the expressions ranges::cend(\( E \)) and ranges::cbegin(\( E \)) model sentinel_for<\( S, I \)>. If \( S \) models input_iterator, then \( S \) also models constant_iterator. — end note]

26.3.6 ranges::rbegin

The name ranges::rbegin denotes a customization point object (16.3.3.3.5).

2. Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and \( \text{enable\_borrowed\_range<remove\_cv\_t<T>}> \) is false, ranges::rbegin(\( E \)) is ill-formed.
2. Otherwise, if \( T \) is an array type (9.3.4.5) and \( \text{remove\_all\_extends\_t<T> > } \) is an incomplete type, ranges::rbegin(\( E \)) is ill-formed with no diagnostic required.
3. Otherwise, if \( \text{auto}(\text{t.rbegin}()) \) is a valid expression whose type models \text{input\_or\_output\_iterator}, ranges::rbegin(\( E \)) is expression-equivalent to \( \text{auto}(\text{t.rbegin}()) \).
4. Otherwise, if \( T \) is a class or enumeration type and \( \text{auto}(\text{rbegin}(t)) \) is a valid expression whose type models input_or_output_iterator where the meaning of rbegin is established as-if by performing argument-dependent lookup only (6.5.4), then ranges::rbegin(\( E \)) is expression-equivalent to that expression.
5. Otherwise, if both ranges::begin(\( t \)) and ranges::end(\( t \)) are valid expressions of the same type which models bidirectional_iterator (25.3.4.12), ranges::rbegin(\( E \)) is expression-equivalent to
   \( \text{make\_reverse\_iterator}(\text{ranges::end}(\text{t})) \).

6. Otherwise, ranges::rbegin(\( E \)) is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::rbegin(\( E \)) appears in the immediate context of a template instantiation. — end note]

[Note 2: Whenever ranges::rbegin(\( E \)) is a valid expression, its type models \text{input\_or\_output\_iterator}. — end note]

26.3.7 ranges::rend

The name ranges::rend denotes a customization point object (16.3.3.3.5).

2. Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and \( \text{enable\_borrowed\_range<remove\_cv\_t<T>}> \) is false, ranges::rend(\( E \)) is ill-formed.
2. Otherwise, if \( T \) is an array type (9.3.4.5) and \( \text{remove\_all\_extends\_t<T> > } \) is an incomplete type, ranges::rend(\( E \)) is ill-formed with no diagnostic required.
3. Otherwise, if \( \text{auto}(\text{t.rend}()) \) is a valid expression whose type models sentinel_for<\( \text{decltype}(\text{ranges::rbegin}(\text{E})), \text{ranges::rend}(\text{E}) \)) is expression-equivalent to \( \text{auto}(\text{t.rend}()) \).
— Otherwise, if T is a class or enumeration type and \(\text{auto}(\text{rend}(t))\) is a valid expression whose type models sentinel_for<decltype(ranges::begin(E))> where the meaning of \(\text{rend}\) is established as-if by performing argument-dependent lookup only (6.5.4), then ranges::rend(E) is expression-equivalent to that expression.

— Otherwise, if both ranges::begin(t) and ranges::end(t) are valid expressions of the same type which models bidirectional_iterator (25.3.4.12), then ranges::rend(E) is expression-equivalent to make_reverse_iterator(ranges::begin(t)).

— Otherwise, ranges::rend(E) is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::rend(E) appears in the immediate context of a template instantiation. — end note]

2.6 [range.access.crbegin]

The name ranges::crbegin denotes a customization point object (16.3.3.3.5). Given a subexpression E with type T, let t be an lvalue that denotes the reified object for E. Then:

— If E is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::crbegin(E) is ill-formed.

— Otherwise, let U be ranges::begin(possibly-const-range(t)). ranges::crbegin(E) is expression-equivalent to const_iterator<decltype(U)>((U).

2 [Note 1: Whenever ranges::crbegin(E) is a valid expression, its type models input_or_output_iterator and constant_iterator. — end note]

2.3.9 [range.access.crend]

The name ranges::crend denotes a customization point object (16.3.3.3.5). Given a subexpression E with type T, let t be an lvalue that denotes the reified object for E. Then:

— If E is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::crend(E) is ill-formed.

— Otherwise, let U be ranges::rend(possibly-const-range(t)). ranges::crend(E) is expression-equivalent to const_sized_range<decltype(U)>((U).

2 [Note 1: Whenever ranges::crend(E) is a valid expression, the types S and I of the expressions ranges::rend(E) and ranges::crbegin(E) model sentinel_for<S, I>. If S models input_iterator, then S also models constant_iterator. — end note]

2.3.10 [range.prim.size]

The name ranges::size denotes a customization point object (16.3.3.3.5).

2 Given a subexpression E with type T, let t be an lvalue that denotes the reified object for E. Then:

— If T is an array of unknown bound (9.3.4.5), ranges::size(E) is ill-formed.

— Otherwise, if T is an array type, ranges::size(E) is expression-equivalent to auto(extent_v<T>)).

— Otherwise, if disable_sized_range<remove_cv_t<T>> (26.4.3) is false and auto(t.size()) is a valid expression of integer-like type (25.3.4.4), ranges::size(E) is expression-equivalent to auto(t.size()).

— Otherwise, if T is a class or enumeration type, disable_sized_range<remove_cv_t<T>> is false and auto(size(t)) is a valid expression of integer-like type where the meaning of size is established as-if by performing argument-dependent lookup only (6.5.4), then ranges::size(E) is expression-equivalent to that expression.

— Otherwise, if to_unsigned-like(ranges::end(t) - ranges::begin(t)) (26.2) is a valid expression and the types I and S of ranges::begin(t) and ranges::end(t) (respectively) model both sized_sentinel_for<S, I> (25.3.4.8) and forward_iterator<1>, then ranges::size(E) is expression-equivalent to to_unsigned-like(ranges::end(t) - ranges::begin(t)).

— Otherwise, ranges::size(E) is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::size(E) appears in the immediate context of a template instantiation. — end note]
26.3.11 ranges::ssize

The name ranges::ssize denotes a customization point object (16.3.3.3.5).

Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. If ranges::size($t$) is ill-formed, ranges::ssize($E$) is ill-formed. Otherwise let $D$ be make_signed-like-$t<$decltype(ranges::size($t$))> if it is wider than that type; ranges::ssize($E$) is expression-equivalent to static_cast<$D$>(ranges::size($t$)).

26.3.12 ranges::empty

The name ranges::empty denotes a customization point object (16.3.3.3.5).

Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

- If $T$ is an array of unknown bound (9.3.4.5), ranges::empty($E$) is ill-formed.
- Otherwise, if bool($t$.empty()) is a valid expression, ranges::empty($E$) is expression-equivalent to bool($t$.empty()).
- Otherwise, if (ranges::size($t$) == 0) is a valid expression, ranges::empty($E$) is expression-equivalent to (ranges::size($t$) == 0).
- Otherwise, if bool(ranges::begin($t$) == ranges::end($t$)) is a valid expression and the type of ranges::begin($t$) models forward_iterator, ranges::empty($E$) is expression-equivalent to bool(ranges::begin($t$) == ranges::end($t$)).
- Otherwise, ranges::empty($E$) is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::empty($E$) appears in the immediate context of a template instantiation. — end note]

26.3.13 ranges::data

The name ranges::data denotes a customization point object (16.3.3.3.5).

Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

- If $E$ is an rvalue and enable_borrowed_range<remove_cv_t<$T$>> is false, ranges::data($E$) is ill-formed.
- Otherwise, if $T$ is an array type (9.3.4.5) and remove_all_extents_t<$T$> is an incomplete type, ranges::data($E$) is ill-formed with no diagnostic required.
- Otherwise, if auto($t$.data()) is a valid expression of pointer to object type, ranges::data($E$) is expression-equivalent to auto($t$.data()).
- Otherwise, if ranges::begin($t$) is a valid expression whose type models contiguous_iterator, ranges::data($E$) is expression-equivalent to to_address(ranges::begin($t$)).
- Otherwise, ranges::data($E$) is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::data($E$) appears in the immediate context of a template instantiation. — end note]

26.3.14 ranges::cdata

The name ranges::cdata denotes a customization point object (16.3.3.3.5). Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

- If $E$ is an rvalue and enable_borrowed_range<remove_cv_t<$T$>> is false, ranges::cdata($E$) is ill-formed.
- Otherwise, ranges::cdata($E$) is expression-equivalent to as-const-pointer(ranges::data(possibly-const-range($t$))).

[Note 1: Whenever ranges::cdata($E$) is a valid expression, it has pointer to constant object type. — end note]
26.4 Range requirements [range.req]

26.4.1 General [range.req.general]

Ranges are an abstraction that allows a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `input_or_output_iterator` (25.3.4.6). Calling `ranges::end` on a range returns an object whose type `S`, together with the type `I` of the object returned by `ranges::begin`, models `sentinel_for<S, I>`.

The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

The `range` concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The `sized_range` concept refines `range` with the requirement that `ranges::size` be amortized $O(1)$.

Several refinements of `range` group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `random_access_iterator` (25.3.4.13).

(Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

26.4.2 Ranges [range.range]

The `range` concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```cpp
template<class T>
concept range =
    requires(T& t) {
        ranges::begin(t); // sometimes equality-preserving (see below)
        ranges::end(t);
    };
```

Given an expression `t` such that `decltype((t))` is `T&`, `T` models `range` only if

1. `ranges::begin(t), ranges::end(t)` denotes a range (25.3.1),
2. both `ranges::begin(t)` and `ranges::end(t)` are amortized constant time and non-modifying, and
3. if the type of `ranges::begin(t)` models `forward_iterator`, `ranges::begin(t)` is equality-preserving.

[Note 1: Equality preservation of both `ranges::begin` and `ranges::end` enables passing a range whose iterator type models `forward_iterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `forward_iterator`, it is possible for repeated calls to not return equal values or to not be well-defined. —end note]

```cpp
template<class T>
concept borrowed_range =
    range<T> && (is_lvalue_reference_v<T> || enable_borrowed_range<remove_cvref_t<T>>);
```

Let `U` be `remove_reference_t<T>` if `T` is an rvalue reference type, and `T` otherwise. Given a variable `u` of type `U`, `T` models `borrowed_range` only if the validity of iterators obtained from `u` is not tied to the lifetime of that variable.

[Note 2: Since the validity of iterators is not tied to the lifetime of a variable whose type models `borrowed_range`, a function with a parameter of such a type can return iterators obtained from it without danger of dangling. —end note]

```cpp
template<class T>
constexpr bool enable_borrowed_range = false;
```

Remarks: Pursuant to 16.4.5.2.1, users may specialize `enable_borrowed_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

[Example 1: Each specialization `S` of class template `subrange` (26.5.4) models `borrowed_range` because

```cpp
    enable_borrowed_range<S> is specialized to have the value true, and
```
7.2  S’s iterators do not have validity tied to the lifetime of an S object because they are “borrowed” from some other range.

— end example]

26.4.3 Sized ranges

The sized_range concept refines range with the requirement that the number of elements in the range can be determined in amortized constant time using ranges::size.

```cpp
template<class T>
concept sized_range =
  range<T> && requires(T& t) { ranges::size(t); };  // (2.1)
```

26.4.4 Views

The view concept specifies the requirements of a range type that has the semantic properties below, which make it suitable for use in constructing range adaptor pipelines (26.7).

```cpp
template<class T>
concept view =
  range<T> && movable<T> && enable_view<T>;  // (2.1)
```

1. Example 1: Examples of views are:
   (4.1) A range type that wraps a pair of iterators.
   (4.2) A range type that holds its elements by shared_ptr and shares ownership with all its copies.
   (4.3) A range type that generates its elements on demand.

A container such as vector<string> does not meet the semantic requirements of view since copying the container copies all of the elements, which cannot be done in constant time. — end example]
Since the difference between range and view is largely semantic, the two are differentiated with the help of enable_view.

```
template<class T>
constexpr bool is-derived-from-view-interface = see below;       // exposition only
```

For a type T, is-derived-from-view-interface<T> is true if and only if T has exactly one public base class view_interface<U> for some type U and T has no base classes of type view_interface<V> for any other type V.

Remarks: Pursuant to 16.4.5.2.1, users may specialize enable_view to true for cv-unqualified program-defined types which model view, and false for types which do not. Such specializations shall be usable in constant expressions (7.7) and have type const bool.

### 26.4.5 Other range refinements

The output_range concept specifies requirements of a range type for which ranges::begin returns a model of output_iterator (25.3.4.10). input_range, forward_range, bidirectional_range, and random_access_range are defined similarly.

```
template<class R, class T>
concept output_range =
    range<R> && output_iterator<iterator_t<R>, T>;
```

```
template<class T>
concept input_range =
    range<T> && input_iterator<iterator_t<T>>;
```

```
template<class T>
concept forward_range =
    input_range<T> && forward_iterator<iterator_t<T>>;
```

```
template<class T>
concept bidirectional_range =
    forward_range<T> && bidirectional_iterator<iterator_t<T>>;
```

```
template<class T>
concept random_access_range =
    bidirectional_range<T> && random_access_iterator<iterator_t<T>>;
```

contiguous_range additionally requires that the ranges::data customization point object (26.3.13) is usable with the range.

```
template<class T>
concept contiguous_range =
    random_access_range<T> && contiguous_iterator<iterator_t<T>> &&
    requires(T& t) {
        { ranges::data(t) } -> same_as<add_pointer_t<range_reference_t<T>>};
    }
```

Given an expression t such that decltype((t)) is T&, T models contiguous_range only if to_address(ranges::begin(t)) == ranges::data(t) is true.

The common_range concept specifies requirements of a range type for which ranges::begin and ranges::end return objects of the same type.

[Example 1: The standard containers (Clause 24) model common_range. — end example]

```
template<class T>
concept common_range =
    range<T> && same_as<iterator_t<T>>, sentinel_t<T>>;
```
template<class R>
constexpr bool is-initializer-list = see below;  // exposition only

For a type R, is-initializer-list<R> is true if and only if remove_cvref_t<R> is a specialization of initializer_list.

The viewable_range concept specifies the requirements of a range type that can be converted to a view safely.

template<class T>
concept viewable_range =
  range<T> &&
  ((view<remove_cvref_t<T>>, T) ||
  (!view<remove_cvref_t<T>> &&
  (is_lvalue_reference_v<T> || (movable<remove_reference_t<T>> && !is-initializer-list<T>))));

The constant_range concept specifies the requirements of a range type whose elements are not modifiable.

template<class T>
concept constant_range =
  input_range<T> && constant_iterator<iterator_t<T>>;

26.5 Range utilities [range.utility]

26.5.1 General [range.utility.general]

The components in 26.5 are general utilities for representing and manipulating ranges.

26.5.2 Helper concepts [range.utility.helpers]

Many of the types in subclause 26.5 are specified in terms of the following exposition-only concepts:

template<class R>
concept simple-view =
  view<R> && range<range<const R>> &&
  same_as<iterator_t<R>, iterator_t<const R>> &&
  same_as<sentinel_t<R>, sentinel_t<const R>>;

template<class I>
concept has-arrow =
  input_iterator<I> && (is_pointer_v<I> || requires(I i) { i.operator->(); });

template<class T, class U>
concept different-from =
  !same_as<remove_cvref_t<T>, remove_cvref_t<U>>;

template<class R>
concept range-with-movable-references =
  input_range<R> && move_constructible<range_reference_t<R>> &&
  move_constructible<range_rvalue_reference_t<R>>;

26.5.3 View interface [view.interface]

26.5.3.1 General [view.interface.general]

The class template view_interface is a helper for defining view-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

namespace std::ranges {
  template<class D>
  requires is_class_v<D> && same_as<D, remove_cv_t<D>>
  class view_interface {
    private:
      constexpr D& derived() noexcept { // exposition only
        return static_cast<D&>(*this);
      }
      constexpr const D& derived() const noexcept { // exposition only
        return static_cast<const D&>(*this);
      }
  }
}
public:
constexpr bool empty() requires sized_range<D> || forward_range<D> {
    if constexpr (sized_range<D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}
constexpr bool empty() const requires sized_range<const D> || forward_range<const D> {
    if constexpr (sized_range<const D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}
constexpr auto cbegin() requires input_range<D> {
    return ranges::cbegin(derived());
}
constexpr auto cbegin() const requires input_range<const D> {
    return ranges::cbegin(derived());
}
constexpr auto cend() requires input_range<D> {
    return ranges::cend(derived());
}
constexpr auto cend() const requires input_range<const D> {
    return ranges::cend(derived());
}
constexpr explicit operator bool() requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}
constexpr explicit operator bool() const requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}
constexpr decltype(auto) front() requires forward_range<D>;
constexpr decltype(auto) front() const requires forward_range<const D>;
constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
constexpr decltype(auto) back() const requires bidirectional_range<const D> && common_range<const D>;
template<random_access_range R = D>
constexpr decltype(auto) operator[](range_difference_t<R> n) {
    return ranges::begin(derived())[n];
}
template<random_access_range R = const D>
constexpr decltype(auto) operator[](range_difference_t<R> n) const {
    return ranges::begin(derived())[n];
}
}

2 The template parameter D for view_interface may be an incomplete type. Before any member of the resulting specialization of view_interface other than special member functions is referenced, D shall be complete, and model both derived_from<view_interface<D>> and view.

26.5.3.2 Members

constexpr decltype(auto) front() requires forward_range<D>;  
constexpr decltype(auto) front() const requires forward_range<const D>;

1 Preconditions: !empty() is true.

2 Effects: Equivalent to: return *ranges::begin(derived());

constexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;  
constexpr decltype(auto) back() const requires bidirectional_range<const D> && common_range<const D>;

3 Preconditions: !empty() is true.

4 Effects: Equivalent to: return *ranges::prev(ranges::end(derived()));

26.5.4 Sub-ranges

26.5.4.1 General

1 The subrange class template combines together an iterator and a sentinel into a single object that models the view concept. Additionally, it models the sized_range concept when the final template parameter is subrange_kind::sized.

namespace std::ranges {

    template<class From, class To>
    concept uses-nonqualification-pointer-conversion = // exposition only
        is_pointer_v<From> && is_pointer_v<To> &&
        !convertible_to<remove_pointer_t<From>(*[]), remove_pointer_t<To>(*[])>;  

template<class From, class To>
    concept convertible-to-non-slicing = // exposition only
        convertible_to_from<From, To> &&
        !uses-nonqualification-pointer-conversion<decay_t<From>, decay_t<To>>;

    template<class T, class U, class V>
    concept pair-like-convertible-from = // exposition only
        !range<T> && !is_reference_v<T> && pair-like<T> &&
        constructible_from<T, U, V> &&
        convertible-to-non-slicing<U, tuple_element_t<0, T>>, tuple_element_t<1, T>> &&
        convertible_to<V, tuple_element_t<1, T>>;

    template<input_or_output_iterator I, sentinel_for<I> S = I, subrange_kind K = sized_sentinel_for<S, I> ? subrange_kind::sized : subrange_kind::unsized>
        requires (K == subrange_kind::sized || !sized_sentinel_for<S, I>)
    class subrange : public view_interface<subrange<I, S, K>> {

private:
    static constexpr bool StoreSize = // exposition only
        K == subrange_kind::sized && !sized_sentinel_for<S, I>;
    I begin_ = I();
    S end_ = S();

    make_unsigned_like_t<iter_difference_t<I>> size_ = 0;

public:
    subrange() requires default_initializable<I> = default;

    constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);
constexpr subrange(convertible-to-non-slicing<I> auto i, S s,  
    make-unsigned-like-t<iter_difference_t<I>> n)  
    requires (K == subrange_kind::sized);

template<different-from<subrange> R>  
    requires borrowed_range<R> &&  
    convertible-to-non-slicing<iterator_t<R>, I> &&  
    convertible_to<sentinel_t<R>, S>  
    constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);

template<borrowed_range R>  
    requires convertible-to-non-slicing<iterator_t<R>, I> &&  
    convertible_to<sentinel_t<R>, S>  
    constexpr subrange(R&& r, make-unsigned-like-t<iter_difference_t<I>> n)  
    requires (K == subrange_kind::sized)  
    : subrange(ranges::begin(r), ranges::end(r), n) {}  

template<different-from<subrange> PairLike>  
    requires pair-like-convertible-from<PairLike, const I&, const S&>  
    constexpr subrange(PairLike) const;  

castexpr I begin() const requires copyable<I>;  
[[nodiscard]] constexpr I begin() requires (!copyable<I>);  
constexpr S end() const;  
constexpr bool empty() const;  
constexpr make-unsigned-like-t<iter_difference_t<I>> size() const  
    requires (K == subrange_kind::sized);  
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &  
    requires forward_iterator<I>;  
[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;  
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const  
    requires bidirectional_iterator<I>;  
constexpr subrange& advance(iter_difference_t<I> n);

26.5.4.2 Constructors and conversions

constexpr subrange(convertible-to-non-slicing<I> auto i, S s) requires (!StoreSize);

1 Preconditions: [i, s) is a valid range.

2 Effects: Initializes begin_ with std::move(i) and end_ with s.
constexpr subrange(convertible-to-non-slicing<I> auto i, S s, make-unsigned-like-t<iter_difference_t<I>> n)
requires (K == subrange_kind::sized);

Preconditions: [i, s) is a valid range, and n == to-unsigned-like(ranges::distance(i, s)) is true.

Effects: Initializes begin_ with std::move(i) and end_ with s. If StoreSize is true, initializes size_ with n.

[Note 1: Accepting the length of the range and storing it to later return from size() enables subrange to model sized_range even when it stores an iterator and sentinel that do not model sized_sentinel_for. — end note]

template<different-from<subrange> R>
requires borrowed_range<R> &&
    convertible-to-non-slicing<iterator_t<R>, I> &&
    convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);

Effects: Equivalent to:

— (6.1) If StoreSize is true, subrange(r, static_cast<decltype(size_)->ranges::size(r))).
— (6.2) Otherwise, subrange(ranges::begin(r), ranges::end(r)).

template<different-from<subrange> PairLike>
requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;

Effects: Equivalent to: return PairLike(begin_, end_);

26.5.4.3 Accessors

constexpr I begin() const requires copyable<I>;

Effects: Equivalent to: return begin_;

[[nodiscard]] constexpr I begin() requires (!copyable<I>);

Effects: Equivalent to: return std::move(begin_);

constexpr S end() const;

Effects: Equivalent to: return end_;

castexpr bool empty() const;

Effects: Equivalent to: return begin_ == end_;

castexpr make-unsigned-like-t<iter_difference_t<I>> size() const
requires (K == subrange_kind::sized);

Effects:

— (5.1) If StoreSize is true, equivalent to: return size_;
— (5.2) Otherwise, equivalent to: return to-unsigned-like(end_ - begin_);

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &
requires forward_iterator<I>;

Effects: Equivalent to:

auto tmp = *this;
 tmp.advance(n);
 return tmp;

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;

Effects: Equivalent to:

advance(n);
 return std::move(*this);
```cpp
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const
requires bidirectional_iterator<I>;

Effects: Equivalent to:
auto tmp = *this;
tmp.advance(-n);
return tmp;

constexpr subrange& advance(iter_difference_t<I> n);

Effects: Equivalent to:
if constexpr (bidirectional_iterator<I>) {
  if (n < 0) {
    ranges::advance(begin_, n);
    if constexpr (StoreSize)
      size_ += to-unsigned-like(-n);
    return *this;
  }
}

auto d = n - ranges::advance(begin_, n, end_);
if constexpr (StoreSize)
  size_ -= to-unsigned-like(d);
return *this;

template<size_t N, class I, class S, subrange_kind K>
requires ((N == 0 && copyable<I>) || N == 1)
constexpr auto get(const subrange<I, S, K>& r);

template<size_t N, class I, class S, subrange_kind K>
requires (N < 2)
constexpr auto get(subrange<I, S, K>&& r);

Effects: Equivalent to:
if constexpr (N == 0)
  return r.begin();
else
  return r.end();

26.5.5 Dangling iterator handling

The type dangling is used together with the template aliases borrowed_iterator_t and borrowed_subrange_t. When an algorithm that typically returns an iterator into, or a subrange of, a range argument is called with an rvalue range argument that does not model borrowed_range (26.4.2), the return value possibly refers to a range whose lifetime has ended. In such cases, the type dangling is returned instead of an iterator or subrange.

namespace std::ranges {
  struct dangling {
    constexpr dangling() noexcept = default;
    constexpr dangling(auto&&...) noexcept {}  
  }
};

[Example 1:

```cpp
vector<int> f();
auto result1 = ranges::find(f(), 42); // #1
static_assert(same_as<decaytype(result1), ranges::dangling>);
auto vec = f();
auto result2 = ranges::find(vec, 42); // #2
static_assert(same_as<decaytype(result2), vector<int>::iterator>);
auto result3 = ranges::find(ranges::subrange{vec}, 42); // #3
static_assert(same_as<decaytype(result3), vector<int>::iterator>);
```

The call to ranges::find at #1 returns ranges::dangling since f() is an rvalue vector; it is possible for the vector to be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both return iterators since the lvalue vec and specializations of subrange model borrowed_range. — end example]
For a type $R$ that models `range`:

1. if $R$ models `borrowed_range`, then `borrowed_iterator_t<R>` denotes `iterator_t<R>`, and `borrowed_subrange_t<R>` denotes `subrange<iterator_t<R>>`;
2. otherwise, both `borrowed_iterator_t<R>` and `borrowed_subrange_t<R>` denote `dangling`.

### 26.5.6 Class template `elements_of` [range.elementsof]

Specializations of `elements_of` encapsulate a range and act as a tag in overload sets to disambiguate when a range should be treated as a sequence rather than a single value.

**Example 1:**
```cpp
template<bool YieldElements>
generator<any> f(ranges::input_range auto&& r) {
  if constexpr (YieldElements)
    co_yield ranges::elements_of(r);  // yield each element of r
  else
    co_yield r;                      // yield r as a single value
}
```

### 26.5.7 Range conversions [range.utility.conv]

#### 26.5.7.1 General [range.utility.conv.general]

1. The range conversion functions construct an object (usually a container) from a range, by using a constructor taking a range, a `from_range_t` tagged constructor, or a constructor taking a pair of iterators, or by inserting each element of the range into the default-constructed object.
2. `ranges::to` is applied recursively, allowing the conversion of a range of ranges.

**Example 1:**
```cpp
string_view str = "the quick brown fox";
auto words = views::split(str, ' ') | to<vector<string>>();
// words is vector<string>\{"the", "quick", "brown", "fox"\}
```

3. Let `reservable-container` be defined as follows:

   ```cpp
template<class Container>
   constexpr bool reservable-container =
   // exposition only
   sized_range<Container>&
   requires(Container& c, range_size_t<Container> n) {
     c.reserve(n);
     { c.capacity() } -> same_as<decltype(n)>;
     { c.max_size() } -> same_as<decltype(n)>;
   };
```

4. Let `container-insertable` be defined as follows:

   ```cpp
template<class Container, class Ref>
   constexpr bool container-insertable =
   // exposition only
   requires(Container& c, Ref&& ref) {
     requires (requires { c.push_back(std::forward<Ref>(ref)); } ||
                requires { c.insert(c.end(), std::forward<Ref>(ref)); });
   };
```
Let `container-inserter` be defined as follows:

```cpp
template<class Ref, class Container>
constexpr auto container-inserter(Container& c) { /* exposition only */
  if constexpr (requires { c.push_back(declval<Ref>()); })
    return back_inserter(c);
  else
    return inserter(c, c.end());
}
```

## 26.5.7.2 ranges::to

```cpp
template<class C, input_range R, class... Args> requires (!view<C>)
constexpr C to(R&& r, Args&&... args);
```

**Mandates**: `C` is a cv-unqualified class type.

**Returns**: An object of type `C` constructed from the elements of `r` in the following manner:

1. If `C` does not satisfy `input_range` or `convertible_to<range_reference_t<R>, range_value_t<C>>` is true:
   - If `constructible_from<C, R, Args...>` is true:
     ```cpp
     C(std::forward<R>(r), std::forward<Args>(args)...)
     ```
   - Otherwise, if `constructible_from<C, from_range_t, R, Args...>` is true:
     ```cpp
     C(from_range, std::forward<R>(r), std::forward<Args>(args)...)
     ```
   - Otherwise, if
     ```cpp
     - common_range<R> is true,
     ```
     ```cpp
     - the qualified-id iterator_traits<iterator_t<R>>::iterator_category is valid and
       denotes a type that models `derived_from<input_iterator_tag>`, and
     ```
     ```cpp
     - constructible_from<C, iterator_t<R>, sentinel_t<R>, Args...>` is true:
       ```cpp
       C(ranges::begin(r), ranges::end(r), std::forward<Args>(args)...)
       ```
     - Otherwise, if
       ```cpp
       - constructible_from<C, Args...>` is true, and
       ```cpp
       - container-insertable<C, range_reference_t<R>>` is true:
         ```cpp
         C c(std::forward<Args>(args)...);
         if constexpr (sized_range<R> && reservable-container<C>)
           c.reserve(static_cast<range_size_t<C>>(ranges::size(r)));
         ranges::copy(r, container-inserter<range_reference_t<R>>(c));
         ```
     - Otherwise, the program is ill-formed.
   - Otherwise, if `input_range<range_reference_t<R>>` is true:
     ```cpp
to<r | views::transform([](auto&& elem) { return to<range_value_t<C>>(std::forward<decltype(elem)>(elem)); }), std::forward<Args>(args)...>;
```  
2. Otherwise, the program is ill-formed.

```cpp
template<template<class...> class C, input_range R, class... Args>
constexpr auto to(R&& r, Args&&... args);
```

Let `input_iterator` be an exposition-only type:

```cpp
struct input_iterator { // exposition only
  using iterator_category = input_iterator_tag;
  using value_type = range_value_t<R>;
  using difference_type = ptrdiff_t;
  using pointer = add_pointer_t<range_reference_t<R>>;
  using reference = range_reference_t<R>;
  reference operator*() const;
  pointer operator->() const;
  input_iterator& operator++();
  input_iterator operator++(int);
};
```
bool operator==(const input_iterator&) const;
};

[Note 1: input_iterator meets the syntactic requirements of Cpp17InputIterator. — end note]

Let DEDUCE_EXPR be defined as follows:

1. \( C(\declval<R>(), \declval<Args>()...) \) if that is a valid expression,
2. otherwise, \( C(\text{from} \_ \text{range}, \declval<R>(), \declval<Args>()...) \) if that is a valid expression,
3. otherwise,
   \( C(\declval<input iterator>()), \declval<input iterator>(), \declval<Args>()...) \) if that is a valid expression,
4. otherwise, the program is ill-formed.

Returns: \( \text{to}(<\text{decltype(DEDUCE_EXPR)}>(\text{std::forward}<R>(r), \text{std::forward}<\text{Args}>(\text{args})...)). \)

26.5.7.3 ranges::to adaptors

template<class C, class... Args> requires (!view<C>)
constexpr auto to(Args&&... args);

template<template<class...> class C, class... Args>
constexpr auto to(Args&&... args);

Mandates: For the first overload, \( C \) is a cv-unqualified class type.

Returns: A range adaptor closure object (26.7.2) \( f \) that is a perfect forwarding call wrapper (22.10.4) with the following properties:

1. It has no target object.
2. Its bound argument entities \( \text{bound args} \) consist of objects of types \( \text{decay_t<Args>}... \) direct non-list-initialized with \( \text{std::forward<Args>(args)}... \), respectively.
3. Its call pattern is \( \text{to}<C>(r, \text{bound args})... \), where \( r \) is the argument used in a function call expression of \( f \).

26.6 Range factories

26.6.1 General

Subclause 26.6 defines range factories, which are utilities to create a view.

Range factories are declared in namespace \text{std::ranges::views}.

26.6.2 Empty view

26.6.2.1 Overview

[Example 1:

auto e = views::empty<int>;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
— end example]

26.6.2.2 Class template empty_view

namespace std::ranges {

template<class T>
requires is_object_v<T>
class empty_view : public view_interface<empty_view<T>> {
public:
    static constexpr T* begin() noexcept { return nullptr; }
    static constexpr T* end() noexcept { return nullptr; }
    static constexpr T* data() noexcept { return nullptr; }
    static constexpr size_t size() noexcept { return 0; }
    static constexpr bool empty() noexcept { return true; }
};

}
26.6.3 Single view  
26.6.3.1 Overview  

single_view produces a view that contains exactly one element of a specified value.

The name views::single denotes a customization point object (16.3.3.3.5). Given a subexpression E, the expression views::single(E) is expression-equivalent to single_view<decay_t<decltype((E))>>(E).

[Example 1:  
  for (int i : views::single(4))  
    cout << i; // prints 4  
— end example]

26.6.3.2 Class template single_view

namespace std::ranges {  
  template<move_constructible T>  
  requires is_object_v<T>  
  class single_view : public view_interface<single_view<T>> {  
  private:  
    movable-box<T> value_;  
    // exposition only (see 26.7.3)
  public:  
    single_view() requires default_initializable<T> = default;  
    constexpr explicit single_view(const T& t) requires copy_constructible<T>;  
    constexpr explicit single_view(T&& t);  
    template<class... Args>  
    requires constructible_from<T, Args...>  
    constexpr explicit single_view(in_place_t, Args&&... args);  

    constexpr T* begin() noexcept;  
    constexpr const T* begin() const noexcept;  
    constexpr T* end() noexcept;  
    constexpr const T* end() const noexcept;  
    static constexpr size_t size() noexcept;  
    constexpr T* data() noexcept;  
    constexpr const T* data() const noexcept;  

    template<class T>  
    single_view(T) -> single_view<T>;
  }

  constexpr explicit single_view(const T& t) requires copy_constructible<T>;  
  
  Effects: Initializes value_ with t.

  constexpr explicit single_view(T&& t);  
  
  Effects: Initializes value_ with std::move(t).

  template<class... Args>  
  requires constructible_from<T, Args...>  
  constexpr explicit single_view(in_place_t, Args&&... args);  

  Effects: Initializes value_ as if by value_{in_place, std::forward<Args>(args)...}.

  constexpr T* begin() noexcept;  
  constexpr const T* begin() const noexcept;  

  Effects: Equivalent to: return data();

  constexpr T* end() noexcept;  
  constexpr const T* end() const noexcept;  

  Effects: Equivalent to: return data() + 1;

  static constexpr size_t size() noexcept;  

  Effects: Equivalent to: return 1;
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Effects: Equivalent to: return value_.operator->();

26.6.4  Iota view
[range.iota]
26.6.4.1  Overview
[range.iota.overview]

iota_view generates a sequence of elements by repeatedly incrementing an initial value.

The name views::iota denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expressions views::iota(E) and views::iota(E, F) are expression-equivalent to iota_view(E) and iota_view(E, F), respectively.

[Example 1:
for (int i : views::iota(1, 10))
    cout << i << ' '; // prints 1 2 3 4 5 6 7 8 9
—end example]

26.6.4.2  Class template iota_view
[range.iota.view]

namespace std::ranges {

    template<class I>
    concept decrementable = see below; // exposition only

    template<class I>
    concept advanceable = see below; // exposition only

    template<weakly_incrementable W, semiregular Bound = unreachable_sentinel_t>
    requires weakly-equality-comparable-with<W, Bound> && copyable<W>
    class iota_view : public view_interface<iota_view<W, Bound>> { // exposition only
        private:
            // 26.6.4.3, class iota_view::iterator
            struct iterator;
            // 26.6.4.4, class iota_view::sentinel
            struct sentinel;

            W value_ = W(); // exposition only
            Bound bound_ = Bound(); // exposition only

        public:
            iota_view() requires default_initializable<W> = default;
            constexpr explicit iota_view(W value);
            constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
            constexpr explicit iota_view(iterator first, see below last);

            constexpr iterator begin() const;
            constexpr auto end() const requires same_as<W, Bound>;
            constexpr iterator end() const requires same_as<W, Bound>;

            constexpr bool empty() const;
            constexpr auto size() const requires see below;
        };

    template<class W, class Bound>
    requires (!is-integer-like<W> || !is-integer-like<Bound> ||
            (is-signed-integer-like<W> == is-signed-integer-like<Bound>))
    iota_view(W, Bound) -> iota_view<W, Bound>;
    }

Let IOTA-DIFF-T(W) be defined as follows:

(1.1)  If W is not an integral type, or if it is an integral type and sizeof(iter_difference_t<W>) is greater than sizeof(W), then IOTA-DIFF-T(W) denotes iter_difference_t<W>.
— Otherwise, $\text{IOTA-DIFF-T}(W)$ is a signed integer type of width greater than the width of $W$ if such a type exists.

— Otherwise, $\text{IOTA-DIFF-T}(W)$ is an unspecified signed-integer-like type (25.3.4.4) of width not less than the width of $W$.

[Note 1: It is unspecified whether this type satisfies weakly_incrementable. — end note]

The exposition-only decrementable concept is equivalent to:

```cpp
template<class I>
concept decrementable = // exposition only
    incrementable<I> && requires(I i) {
        { --i } -> same_as<I&>;
        { i-- } -> same_as<I>;
    };
```

When an object is in the domain of both pre- and post-decrement, the object is said to be decrementable.

Let $a$ and $b$ be equal objects of type $I$. $I$ models decrementable only if

1. If $a$ and $b$ are decrementable, then the following are all true:
   1.1. $\text{addressof}(-a) == \text{addressof}(a)$
   1.2. $\text{bool}(a-- == b)$
   1.3. $\text{bool}(((\text{void})a--, a) == --b)$
   1.4. $\text{bool}(++((-a) == b)$.

2. If $a$ and $b$ are incrementable, then $\text{bool}(-(-++a) == b)$.

The exposition-only advanceable concept is equivalent to:

```cpp
template<class I>
concept advanceable = // exposition only
    decrementable<I> && totally_ordered<I> &&
    requires(I i, const I j, const IOTA-DIFF-T(I) n) {
        { i += n } -> same_as<I&>;
        { i -= n } -> same_as<I&>;
        I(j + n);
        I(n + j);
        I(j - n);
        { j - j } -> convertible_to<IOTA-DIFF-T(I)>;
    };
```

Let $D$ be $\text{IOTA-DIFF-T}(I)$. Let $a$ and $b$ be objects of type $I$ such that $b$ is reachable from $a$ after $n$ applications of $++a$, for some value $n$ of type $D$. $I$ models advanceable only if

1. $(a += n)$ is equal to $b$.
2. $\text{addressof}(a += n)$ is equal to $\text{addressof}(a)$.
3. $I(a + n)$ is equal to $(a += n)$.
4. For any two positive values $x$ and $y$ of type $D$, if $I(a + D(x + y))$ is well-defined, then $I(a + D(x + y))$ is equal to $I(I(a + x) + y)$.
5. $I(a + D(0))$ is equal to $a$.
6. If $I(a + D(n - 1))$ is well-defined, then $I(a + n)$ is equal to $\lfloor(I c) \{ \text{return } ++c; \}(I(a + D(n - 1)))$.
7. $(b += -n)$ is equal to $a$.
8. $(b -= n)$ is equal to $a$.
9. $\text{addressof}(b -= n)$ is equal to $\text{addressof}(b)$.
10. $I(b - n)$ is equal to $(b -= n)$.
11. $D(b - a)$ is equal to $n$.
12. $D(a - b)$ is equal to $D(-n)$.
13. $\text{bool}(a <= b)$ is true.

§ 26.6.4.2 1181
constexpr explicit iota_view(W value);

**Preconditions:** Bound denotes unreachable_sentinel_t or Bound() is reachable from value. When W and Bound model totally_ordered_with, then bool(value <= Bound()) is true.

**Effects:** Initializes value_ with value.

customexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);

**Preconditions:** Bound denotes unreachable_sentinel_t or bound is reachable from value. When W and Bound model totally_ordered_with, then bool(value <= bound) is true.

**Effects:** Initializes value_ with value and bound_ with bound.

customexpr explicit iota_view(iterator first, see below last);

**Effects:** Equivalent to:

(10.1) If same_as<W, Bound> is true, iota_view(first.value_, last.value_).
(10.2) Otherwise, if Bound denotes unreachable_sentinel_t, iota_view(first.value_, last).
(10.3) Otherwise, iota_view(first.value_, last.bound_).

**Remarks:** The type of last is:

(11.1) If same_as<W, Bound> is true, iterator.
(11.2) Otherwise, if Bound denotes unreachable_sentinel_t, Bound.
(11.3) Otherwise, sentinel.

constexpr iterator begin() const;

**Effects:** Equivalent to: return iterator{value_};

customexpr auto end() const;

**Effects:** Equivalent to:

if constexpr (same_as<Bound, unreachable_sentinel_t>)
    return unreachable_sentinel;
else
    return sentinel{bound_};

customexpr iterator end() const requires same_as<W, Bound>;

**Effects:** Equivalent to: return iterator{bound_};

customexpr bool empty() const;

**Effects:** Equivalent to: return value_ == bound_;

customexpr auto size() const requires see below;

**Effects:** Equivalent to:

if constexpr (is-integer-like<W> && is-integer-like<Bound>)
    return (value_ < 0)
    ? ((bound_ < 0)
        ? to-unsigned-like(-value_) - to-unsigned-like(-bound_) : to-unsigned-like(bound_) + to-unsigned-like(-value_))
    : to-unsigned-like(bound_) - to-unsigned-like(value_);
else
    return to-unsigned-like(bound_ - value_);

**Remarks:** The expression in the requires-clause is equivalent to:

(same_as<W, Bound> && advanceable<W>) || (is-integer-like<W> && is-integer-like<Bound>) || sized_sentinel_for<Bound, W>

### Class iota_view::iterator

namespace std::ranges {
    template<weakly_incrementable W, semiregular Bound>
    requires weakly-equality-comparable-with<W, Bound> && copyable<W>
    struct iota_view<W, Bound>::::iterator {

§ 26.6.4.3
private:
    W value_ = W(); // exposition only

public:
    using iterator_concept = see below; // present only if W models incrementable and
    using iterator_category = input_iterator_tag; // IOTA-DIFF-T(W) is an integral type
    using value_type = W;
    using difference_type = IOTA-DIFF-T(W);

    iterator() requires default_initializable<W> = default;
    constexpr explicit iterator(W value);

        public:
            sentinel() = default;
            constexpr explicit sentinel(Bound bound);

            friend constexpr bool operator==(const iterator& x, const sentinel& y);

            friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
                requires sized_sentinel_for<Bound, W>;

            friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
                requires sized_sentinel_for<Bound, W>;
    }
}

constexpr explicit sentinel(Bound bound);

1 Effects: Initializes bound_ with bound.

friend constexpr bool operator==(const iterator& x, const sentinel& y);

2 Effects: Equivalent to: return x.value_ == y.bound_;

friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
    requires sized_sentinel_for<Bound, W>;

3 Effects: Equivalent to: return x.value_ - y.bound_;

friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
    requires sized_sentinel_for<Bound, W>;

4 Effects: Equivalent to: return -(y - x);

26.6.5 Repeat view

26.6.5.1 Overview

repeat_view generates a sequence of elements by repeatedly producing the same value.

The name views::repeat denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expressions views::repeat(E) and views::repeat(E, F) are expression-equivalent to repeat_view(E) and repeat_view(E, F), respectively.

[Example 1:]
    for (int i : views::repeat(17, 4))
        cout << i << ' ';
    // prints 17 17 17 17
—end example]
struct iterator;  // exposition only
movable-box<T> value_;  // exposition only, see 26.7.3
Bound bound_ = Bound();  // exposition only

public:
repeat_view() requires default_initializable<T> = default;

constexpr explicit repeat_view(const T& value, Bound bound = Bound())
    requires copy_constructible<T>;
constexpr explicit repeat_view(T& value, Bound bound = Bound());
template<class... TArgs, class... BoundArgs>
    requires constructible_from<T, TArgs...> &&
        constructible_from<Bound, BoundArgs...>
constexpr explicit repeat_view(piecewise_construct_t,
    tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});

constexpr iterator begin() const;  
constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
constexpr unreachable_sentinel_t end() const noexcept;  
constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);

constexpr explicit repeat_view(T&& value, Bound bound = Bound());

Preconditions: If Bound is not unreachable_sentinel_t, bound \geq 0.
Effects: Initializes value_ with value and bound_ with bound.

constexpr explicit repeat_view(T& value, Bound bound = Bound());

Preconditions: If Bound is not unreachable_sentinel_t, bound \geq 0.
Effects: Initializes value_ with std::move(value) and bound_ with bound.

template<class... TArgs, class... BoundArgs>
    requires constructible_from<T, TArgs...> &&
        constructible_from<Bound, BoundArgs...>
constexpr explicit repeat_view(piecewise_construct_t,
    tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<>{});

Effects: Initializes value_ with make_from_tuple<T>(std::move(value_args)) and initializes
bound_ with make_from_tuple<Bound>(std::move(bound_args)). The behavior is undefined if Bound
is not unreachable_sentinel_t and bound_ is negative.

constexpr iterator begin() const;
Effects: Equivalent to: return iterator(addressof(*value_));

constexpr iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
Effects: Equivalent to: return iterator(addressof(*value_), bound_);

constexpr unreachable_sentinel_t end() const noexcept;
Effects: Equivalent to: return unreachable_sentinel;

constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
Effects: Equivalent to: return to-unsigned-like(bound_);

26.6.5.3 Class repeat_view::iterator [range.repeat.iterator]
namespace std::ranges {
    template<move_constructible T, semiregular Bound>
    requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
               (integer-like-with-usable-difference-type<Bound> ||
                same_as<Bound, unreachable_sentinel_t>))
    class repeat_view<T, Bound>::::iterator {
        private:
            using index_type = // exposition only
                conditional_t<same_as<Bound, unreachable_sentinel_t>, ptrdiff_t, Bound>;
            const T* value_ = nullptr; // exposition only
            index_type current_ = index_type(); // exposition only

        constexpr explicit iterator(const T* value, index_type b = index_type()); // exposition only
        public:
            using iterator_concept = random_access_iterator_tag;
            using iterator_category = random_access_iterator_tag;
            using value_type = T;
            using difference_type = see below;
            iterator() = default;
            constexpr const T& operator*() const noexcept;
            constexpr iterator& operator++();
            constexpr iterator operator++(int);
            constexpr iterator& operator--();
            constexpr iterator operator--(int);
            constexpr iterator& operator+=(difference_type n);
            constexpr iterator& operator-=(difference_type n);
            constexpr const T& operator[](difference_type n) const noexcept;

            friend constexpr bool operator==(const iterator& x, const iterator& y);
            friend constexpr auto operator<=>(const iterator& x, const iterator& y);
            friend constexpr iterator operator+(iterator i, difference_type n);
            friend constexpr iterator operator+(difference_type n, iterator i);
            friend constexpr iterator operator-(iterator i, difference_type n);
            friend constexpr difference_type operator-(const iterator& x, const iterator& y);
    };

1. If is-signed-integer-like<index-type> is true, the member typedef-name difference_type denotes index-type. Otherwise, it denotes IOTA-DIFF-T(index-type) (26.6.4.2).

2. Preconditions: If Bound is not unreachable_sentinel_t, b ≥ 0.

3. Effects: Initializes value_ with value and current_ with b.

4. Effects: Equivalent to: return *value_;

5. Effects: Equivalent to:
   ++current_;
   return *this;

6. Effects: Equivalent to:

§ 26.6.5.3
auto tmp = *this;
++*this;
return tmp;

constexpr iterator operator--();

Preconditions: If Bound is not unreachable_sentinel_t, current_ > 0.

Effects: Equivalent to:
--current_;
return *this;

constexpr iterator operator--(int);

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator operator+=(difference_type n);

Preconditions: If Bound is not unreachable_sentinel_t, current_ + n ≥ 0.

Effects: Equivalent to:
current_ += n;
return *this;

constexpr iterator operator-=(difference_type n);

Preconditions: If Bound is not unreachable_sentinel_t, current_ − n ≥ 0.

Effects: Equivalent to:
current_ -= n;
return *this;

constexpr const T& operator[](difference_type n) const noexcept;

Effects: Equivalent to: return *(this + n);

friend constexpr bool operator==(const iterator& x, const iterator& y);

Effects: Equivalent to: return x.current_ == y.current_;

friend constexpr auto operator<=>(const iterator& x, const iterator& y);

Effects: Equivalent to: return x.current_<=> y.current_;
The name `views::istream<T>` denotes a customization point object (16.3.3.5). Given a type `T` and a subexpression `E` of type `U`, if `U` models `derived_from<basic_istream<typename U::char_type, typename U::traits_type>>`, then the expression `views::istream<T>(E)` is expression-equivalent to `basic_istream_view<T, typename U::char_type, typename U::traits_type>(E);` otherwise, `views::istream<T>(E)` is ill-formed.

[Example 1:]

```cpp
auto ints = istreamstringstream(“0 1 2 3 4”);
ranges::copy(views::istream<int>(ints), ostream_iterator<int>{cout, “-”});
// prints 0-1-2-3-4-
```

26.6.6.2 Class template `basic_istream_view`

```cpp
namespace std::ranges {
  template<class Val, class CharT, class Traits>
  concept stream-extractable = // exposition only
      requires(basic_istream<CharT, Traits>>& is, Val& t) {
        is >> t;
      };

template<move_val Val, class CharT, class Traits = char_traits<CharT>>
  requires default_initializable<Val> &&
  stream-extractable<Val, CharT, Traits>
  class basic_istream_view : public view_interface<basic_istream_view<Val, CharT, Traits>> {
    public:
      constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

      constexpr default_sentinel_t end() const noexcept;

    private:
      // 26.6.6.3, class basic_istream_view::iterator
      struct iterator; // exposition only
      basic_istream<CharT, Traits>& stream_; // exposition only
      Val value_ = Val(); // exposition only
    };
  }
}
```

1 Effects: Initializes `stream_` with `addressof(stream)`.

2 Effects: Equivalent to: `return default_sentinel;`

26.6.6.3 Class `basic_istream_view::iterator`

```cpp
namespace std::ranges {
  template<move_val Val, class CharT, class Traits>
    requires default_initializable<Val> &&
    stream-extractable<Val, CharT, Traits>
  class basic_istream_view<Val, CharT, Traits>::iterator {
    public:
      using iterator_concept = input_iterator_tag;
      using difference_type = ptrdiff_t;
      using value_type = Val;

      constexpr explicit iterator(basic_istream_view& parent) noexcept;
```
iterator(const iterator&) = delete;
iterator(iterator&&) = default;

iterator& operator=(const iterator&) = delete;
iterator& operator=(iterator&&) = default;

iterator& operator++();
void operator++(int);

Val& operator*() const;
friend bool operator==(const iterator& x, default_sentinel_t);

private:
   basic_istream_view* parent_;  // exposition only
};

constexpr explicit iterator(basic_istream_view& parent) noexcept;

Effects: Initializes parent_ with addressof(parent).

iterator& operator++();

Effects: Equivalent to:
   *parent_->stream_ >> parent_->value_;
   return *this;

void operator++(int);

Effects: Equivalent to +++this.

Val& operator*() const;

Effects: Equivalent to: return parent_->value_;

friend bool operator==(const iterator& x, default_sentinel_t);

Effects: Equivalent to: return !x.parent_->stream_;

26.7 Range adaptors

26.7.1 General

Subclause 26.7 defines range adaptors, which are utilities that transform a range into a view with custom behaviors. These adaptors can be chained to create pipelines of range transformations that evaluate lazily as the resulting view is iterated.

Range adaptors are declared in namespace std::ranges::views.

The bitwise or operator is overloaded for the purpose of creating adaptor chain pipelines. The adaptors also support function call syntax with equivalent semantics.

[Example 1):
   vector<int> ints{0,1,2,3,4,5};
   auto even = [] (int i) { return 0 == i % 2; };
   auto square = [] (int i) { return i * i; };
   for (int i : ints | views::filter(even) | views::transform(square)) {
      cout << i << ' '; // prints 0 4 16
   }
   assert(ranges::equal(ints | views::filter(even), views::filter(ints, even)));
   —end example]

26.7.2 Range adaptor objects

A range adaptor closure object is a unary function object that accepts a range argument. For a range adaptor closure object C and an expression R such that decltype((R)) models range, the following expressions are equivalent:
Given an additional range adaptor closure object $D$, the expression $C \mid D$ produces another range adaptor closure object $E$. $E$ is a perfect forwarding call wrapper (22.10.4) with the following properties:

1.1 — Its target object is an object $d$ of type $\text{decay}_t\langle \text{decltype}((D)) \rangle$ direct-non-list-initialized with $D$.
1.2 — It has one bound argument entity, an object $c$ of type $\text{decay}_t\langle \text{decltype}((C)) \rangle$ direct-non-list-initialized with $C$.
1.3 — Its call pattern is $d(c(\text{arg}))$, where $\text{arg}$ is the argument used in a function call expression of $E$.

The expression $C \mid D$ is well-formed if and only if the initializations of the state entities of $E$ are all well-formed.

Given an object $t$ of type $T$, where

2.1 — $t$ is a unary function object that accepts a range argument,
2.2 — $T$ models $\text{derived}\_\text{from}<\text{range}\_\text{adaptor}\_\text{closure}\langle T \rangle>$,
2.3 — $T$ has no other base classes of type $\text{range}\_\text{adaptor}\_\text{closure}\langle U \rangle$ for any other type $U$, and
2.4 — $T$ does not model $\text{range}$

then the implementation ensures that $t$ is a range adaptor closure object.

The template parameter $D$ for $\text{range}\_\text{adaptor}\_\text{closure}$ may be an incomplete type. If an expression of type $cv\ D$ is used as an operand to the $\mid$ operator, $D$ shall be complete and model $\text{derived}\_\text{from}<\text{range}\_\text{adaptor}\_\text{closure}\langle D \rangle>$. The behavior of an expression involving an object of type $cv\ D$ as an operand to the $\mid$ operator is undefined if overload resolution selects a program-defined $\operatorname{operator}\mid$ function.

If an expression of type $cv\ U$ is used as an operand to the $\mid$ operator, where $U$ has a base class of type $\text{range}\_\text{adaptor}\_\text{closure}\langle T \rangle$ for some type $T$ other than $U$, the behavior is undefined.

The behavior of a program that adds a specialization for $\text{range}\_\text{adaptor}\_\text{closure}$ is undefined.

A range adaptor object is a customization point object (16.3.3.3.5) that accepts a viewable_range as its first argument and returns a view.

If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

If a range adaptor object $\text{adaptor}$ accepts more than one argument, then let $\text{range}$ be an expression such that $\text{decltype}((\text{range}))$ models viewable_range, let $\text{args...}$ be arguments such that $\text{adaptor}(\text{range}, \text{args...})$ is a well-formed expression as specified in the rest of subclause 26.7, and let $\text{BoundArgs}$ be a pack that denotes $\text{decay}_t\langle \text{decltype}((\text{args})) \rangle(\text{args})...$. The expression $\text{adaptor}(\text{args...})$ produces a range adaptor closure object $f$ that is a perfect forwarding call wrapper (22.10.4) with the following properties:

- Its target object is a copy of $\text{adaptor}$.
- Its bound argument entities $\text{bound\_args}$ consist of objects of types $\text{BoundArgs...}$ direct-non-list-initialized with $\operatorname{std}\_\text{::forward}\langle \text{decltype}((\text{args})) \rangle(\text{args})...$, respectively.
- Its call pattern is $\text{adaptor}(r, \text{bound\_args...})$, where $r$ is the argument used in a function call expression of $f$.

The expression $\text{adaptor}(\text{args...})$ is well-formed if and only if the initialization of the bound argument entities of the result, as specified above, are all well-formed.

### 26.7.3 Movable wrapper

Many types in this subclause are specified in terms of an exposition-only class template $\text{movable\_box}\langle T \rangle$. $\text{movable\_box}\langle T \rangle$ behaves exactly like $\text{optional}\langle T \rangle$ with the following differences:

- $\text{movable\_box}\langle T \rangle$ constrains its type parameter $T$ with $\text{move}\_\text{constructible}\langle T \rangle$ & $\text{is}\_\text{object\_v}\langle T \rangle$.
- The default constructor of $\text{movable\_box}\langle T \rangle$ is equivalent to:
  
  ```
  constexpr \text{movable\_box}\langle T \rangle \text{movable\_box}() \text{noexcept}(\text{is\_nothrow\_default\_constructible\_v}\langle T \rangle)
  \text{requires default\_initializable}\langle T \rangle
  \text{movable\_box}\langle \text{in\_place} \rangle \{\}
  ```
- If $\text{copyable}\langle T \rangle$ is not modeled, the copy assignment operator is equivalent to:
constexpr movable-box& operator=(const movable-box& that) noexcept(is_nothrow_copy_constructible_v<T>)
requires copy_constructible<T> {
if (this != addressof(that)) {
if (that) emplace(*that);
else reset();
} return *this;
}

(1.4) — If movable<T> is not modeled, the move assignment operator is equivalent to:
constexpr movable-box& operator=(movable-box&& that) noexcept(is_nothrow_move_constructible_v<T>) {
if (this != addressof(that)) {
if (that) emplace(std::move(*that));
else reset();
} return *this;
}

2 Recommended practice:

(2.1) — If copy_constructible<T> is true, movable-box<T> should store only a T if either T models copyable,
or is_nothrow_move_constructible_v<T> && is_nothrow_copy_constructible_v<T> is true.

(2.2) — Otherwise, movable-box<T> should store only a T if either T models movable or is_nothrow_move_constructible_v<T> is true.

26.7.4 Non-propagating cache [range.nonprop.cache]

Some types in subclause 26.7 are specified in terms of an exposition-only class template non-propagating-cache. non-propagating-cache<T> behaves exactly like optional<T> with the following differences:

(1.1) — non-propagating-cache<T> constrains its type parameter T with is_object_v<T>.

(1.2) — The copy constructor is equivalent to:
constexpr non-propagating-cache(const non-propagating-cache&) noexcept {}

(1.3) — The move constructor is equivalent to:
constexpr non-propagating-cache(non-propagating-cache&& other) noexcept {
other.reset();
}

(1.4) — The copy assignment operator is equivalent to:
constexpr non-propagating-cache& operator=(const non-propagating-cache& other) noexcept {
if (addressof(other) != this)
reset();
return *this;
}

(1.5) — The move assignment operator is equivalent to:
constexpr non-propagating-cache& operator=(non-propagating-cache&& other) noexcept {
reset();
other.reset();
return *this;
}

(1.6) — non-propagating-cache<T> has an additional member function template specified as follows:

template<class I>
constexpr Tk emplace-deref(const I& i); // exposition only

Mandates: The declaration T t(*i); is well-formed for some invented variable t.

[Note 1: If *i is a prvalue of type cv T, there is no requirement that it is movable (9.4.1). — end note]

Effects: Calls reset(). Then direct-non-list-initializes the contained value with *i.

Postconditions: *this contains a value.
Returns: A reference to the new contained value.

Throws: Any exception thrown by the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of \( T \), \(*\this\) does not contain a value, and the previous value (if any) has been destroyed.

\[\text{Note 2: non-propagating-cache enables an input view to temporarily cache values as it is iterated over. — end note}\]

26.7.5 Range adaptor helpers

namespace std::ranges {
    template<class F, class Tuple>
    constexpr auto tuple-transform(F&& f, Tuple&& t) { // exposition only
        return apply([&]<class... Ts>(Ts&&... elements) { 
            return tuple<invoke_result_t<F&, Ts>...>
                (invoke(f, std::forward<Ts>(elements))...);
        }, std::forward<Tuple>(t));
    }

    template<class F, class Tuple>
    constexpr void tuple-for-each(F&& f, Tuple&& t) { // exposition only
        apply([&]<class... Ts>(Ts&&... elements) { 
            (static_cast<void>(invoke(f, std::forward<Ts>(elements))), ...);
        }, std::forward<Tuple>(t));
    }

    template<class T>
    constexpr T& as-lvalue(T&& t) { // exposition only
        return static_cast<T&>(t);
    }
}

26.7.6 All view

26.7.6.1 General

views::all returns a view that includes all elements of its range argument.

The name views::all denotes a range adaptor object (26.7.2). Given a subexpression \( E \), the expression
views::all\( (E) \)

is expression-equivalent to:

1. \( \text{decay-copy}(E) \) if the decayed type of \( E \) models view.
2. Otherwise, \( \text{ref_view}(E) \) if that expression is well-formed.
3. Otherwise, \( \text{owning_view}(E) \).

26.7.6.2 Class template ref_view

ref_view is a view of the elements of some other range.

namespace std::ranges {
    template<range R>
    requires is_object_v<R>
    class ref_view : public view_interface<ref_view<R>> { 
        private:
            R* r_; // exposition only

        public:
            template<different-from<ref_view> T>
            requires see below
            constexpr ref_view(T& t);

            constexpr R& base() const { return *r_; }

            constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
            constexpr sentinel_t<R> end() const { return ranges::end(*r_); }
}

§ 26.7.6.2
constexpr bool empty() const
    requires requires { ranges::empty(*r_); } { return ranges::empty(*r_); }

customexpr auto size() const requires sized_range<R>
    { return ranges::size(*r_); }

customexpr auto data() const requires contiguous_range<R>
    { return ranges::data(*r_); }
};

template<class R>
    ref_view(R&) -> ref_view<R>;

template<
different-from ref_view
>T>
    requires see below
customexpr ref_view(T&& t);  

  Effects: Initializes r_ with addressof(static_cast<R&>(std::forward<T>(t))).

  Remarks: Let FUN denote the exposition-only functions
  void FUN(R&);
  void FUN(R&&) = delete;

  The expression in the requires-clause is equivalent to:
  convertible_to<T, R&> && requires {
    FUN(declval<T>());
  }

§ 26.7.6.3 Class template owning_view

owning_view is a move-only view of the elements of some other range.

namespace std::ranges {
    template<
        range R>
    requires movable<R> && (!is-initializer-list<R>)  // see 26.4.5
    class owning_view : public view_interface<owning_view<R>> { 
        private:
            R r_ = R();  // exposition only

        public:
            owning_view() requires default_initializable<R> = default;
        customexpr owning_view(R&& t);
            owning_view(owning_view&&) = default;
        customexpr operator=(owning_view&&) = default;

            customexpr R& base() & noexcept { return r_; }
            customexpr const R& base() const & noexcept { return r_; }
            customexpr R&& base() && noexcept { return std::move(r_); }
            customexpr const R&& base() && noexcept { return std::move(r_); }

            customexpr iterator_t<R> begin() { return ranges::begin(r_); }
            customexpr sentinel_t<R> end() { return ranges::end(r_); }

            customexpr auto begin() const requires range<
                const R>
                { return ranges::begin(r_); }
            customexpr auto end() const requires range<
                const R>
                { return ranges::end(r_); }

            customexpr bool empty() requires requires { ranges::empty(r_); } { return ranges::empty(r_); }
            customexpr bool empty() const requires requires { ranges::empty(r_); } { return ranges::empty(r_); }

            customexpr auto size() requires sized_range<R>
                { return ranges::size(r_); }
constexpr auto size() const requires sized_range<const R>
{ return ranges::size(r_); }

castexpr auto data() requires contiguous_range<R>
{ return ranges::data(r_); }
castexpr auto data() const requires contiguous_range<const R>
{ return ranges::data(r_); }
};

castexpr owning_view(R&& t);

Effects: Initializes r_ with std::move(t).

26.7.7 As r-value view
26.7.7.1 Overview

as_rvalue_view presents a view of an underlying sequence with the same behavior as the underlying sequence except that its elements are rvalues. Some generic algorithms can be called with an as_rvalue_view to replace copying with moving.

2 The name views::as_value denotes a range adaptor object (26.7.2). Let E be an expression and let T be decltype((E)). The expression views::as_value(E) is expression-equivalent to:

— views::all(E) if same_as<range_rvalue_reference_t<T>, range_reference_t<T>> is true.

— Otherwise, as_rvalue_view(E).

3 [Example 1:]

vector<string> words = {"the", "quick", "brown", "fox", "ate", "a", "pterodactyl");
vector<string> new_words;
ranges::copy(words | views::as_rvalue, back_inserter(new_words));
// moves each string from words into new_words
—end example]

26.7.7.2 Class template as_rvalue_view

namespace std::ranges {

template<view V>
requires input_range<V>
class as_rvalue_view : public view_interface<as_rvalue_view<V>> {

V base_ = V(); // exposition only

public:

as_rvalue_view() requires default_initializable<V> = default;

};

§ 26.7.7.2

1196
26.7.8 Filter view

26.7.8.1 Overview

`filter_view` presents a view of the elements of an underlying sequence that satisfy a predicate.

The name `views::filter` denotes a range adaptor object (26.7.2). Given subexpressions E and P, the expression `views::filter(E, P)` is expression-equivalent to `filter_view(E, P).

[Example 1:] vector<int> is(0, 1, 2, 3, 4, 5, 6); auto evens = views::filter(is, [](int i) { return 0 == i % 2; }); for (int i : evens) cout << i << ' '; // prints 0 2 4 6

—end example—

26.7.8.2 Class template filter_view

namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class filter_view : public view_interface<filter_view<V, Pred>> {
        private:
            V base_ = V(); // exposition only
            movable-box<Pred> pred_; // exposition only

            // 26.7.8.3, class filter_view::iterator
            class iterator; // exposition only

            // 26.7.8.4, class filter_view::sentinel
            class sentinel; // exposition only

        public:
            filter_view() requires default_initializable<V> && default_initializable<Pred> = default;
            constexpr explicit filter_view(V base, Pred pred);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr Pred& pred() const;

            constexpr iterator begin();
            constexpr auto end() { 
                if constexpr (common_range<V>)
                    return iterator{*this, ranges::end(base_)};
                else
                    return sentinel{*this};
            }
        }
    }
}
template<class R, class Pred>
  filter_view(R&&, Pred) -> filter_view<views::all_t<R>, Pred>;
}
constexpr explicit filter_view(V base, Pred pred);

Effects: Initializes base_ with std::move(base) and initializes pred_ with std::move(pred).

constexpr const Pred& pred() const;

Effects: Equivalent to: return *pred_;

constexpr iterator begin();

Preconditions: pred_.has_value() is true.

Returns: {*this, ranges::find_if(base_, ref(*pred_))}.

Remarks: In order to provide the amortized constant time complexity required by the range concept when filter_view models forward_range, this function caches the result within the filter_view for use on subsequent calls.

26.7.8.3 Class filter_view::iterator

namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
  class filter_view<V, Pred>::iterator {
    private:
      iterator_t<V> current_ = iterator_t<V>(); // exposition only
      filter_view* parent_ = nullptr; // exposition only

    public:
      using iterator_concept = see below;
      using iterator_category = see below; // not always present
      using value_type = range_value_t<V>;
      using difference_type = range_difference_t<V>;
      iterator() requires default_initializable<iterator_t<V>> = default;
      constexpr iterator(filter_view& parent, iterator_t<V> current);

    constexpr const iterator_t<V>& base() const & noexcept;
    constexpr iterator_t<V> base() &&;
    constexpr range_reference_t<V> operator*() const;
    constexpr iterator_t<V> operator->() const requires has-arrow<iterator_t<V>> && copyable<iterator_t<V>>;
    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator& operator++(int) requires forward_range<V>;
    constexpr iterator& operator--() requires bidirectional_range<V>;
    constexpr iterator& operator--(int) requires bidirectional_range<V>;

    friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<iterator_t<V>>;
    friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i) noexcept(noexcept(ranges::iter_move(i.current_)));
    friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_))) requires indirectly_swappable<iterator_t<V>>;
  }
}

Modification of the element a filter_view::iterator denotes is permitted, but results in undefined behavior if the resulting value does not satisfy the filter predicate.
iterator::iterator_concept is defined as follows:

1. If V models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
2. Otherwise, if V models forward_range, then iterator_concept denotes forward_iterator_tag.
3. Otherwise, iterator_concept denotes input_iterator_tag.

The member typedef-name iterator_category is defined if and only if V models forward_range. In that case, iterator::iterator_category is defined as follows:

1. Let C denote the type iterator_traits<iterator_t<V>>::iterator_category.
2. If C models derived_from<bidirectional_iterator_tag>, then iterator_category denotes bidirectional_iterator_tag.
3. Otherwise, if C models derived_from<forward_iterator_tag>, then iterator_category denotes forward_iterator_tag.
4. Otherwise, iterator_category denotes C.

```cpp
constexpr iterator(filter_view& parent, iterator_t<V> current);
```

**Effects:** Initializes current_ with std::move(current) and parent_ with addressof(parent).

```cpp
constexpr const iterator_t<V>& base() const & noexcept;
```

**Effects:** Equivalent to: return current_;

```cpp
constexpr iterator_t<V> base() &&;
```

**Effects:** Equivalent to: return std::move(current_);

```cpp
constexpr range_reference_t<V> operator*() const;
```

**Effects:** Equivalent to: return *current_;

```cpp
constexpr iterator_t<V> operator->() const
  requires has-arrow<iterator_t<V>> && copyable<iterator_t<V>>;
```

**Effects:** Equivalent to: return current_;

```cpp
constexpr iterator& operator++();
```

**Effects:** Equivalent to:

```cpp
current_ = ranges::find_if(std::move(++current_), ranges::end(parent_->base_),
  ref(*parent_->pred_));
```

```cpp
return *this;
```

```cpp
constexpr void operator++(int);
```

**Effects:** Equivalent to **++this.

```cpp
constexpr iterator operator++(int) requires forward_range<V>;
```

**Effects:** Equivalent to:

```cpp
auto tmp = *this;
++*this;
return tmp;
```

```cpp
constexpr iterator& operator--() requires bidirectional_range<V>;
```

**Effects:** Equivalent to:

```cpp
do
  --current_;  
while (!invoke(*parent_->pred_, *current_));
```

```cpp
return *this;
```

```cpp
constexpr iterator operator--(int) requires bidirectional_range<V>;
```

**Effects:** Equivalent to:

```cpp
auto tmp = *this;
--*this;
```
friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<iterator_t<V>>;

Effects: Equivalent to: return x.current_ == y.current_
1
friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i) noexcept(noexcept(ranges::iter_move(i.current_)))
15
Effects: Equivalent to: return ranges::iter_move(i.current_);
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_))) requires indirectly_swappable<iterator_t<V>>;
16
Effects: Equivalent to: ranges::iter_swap(x.current_, y.current_).

26.7.8.4 Class filter_view::sentinel

namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::sentinel {
        private:
            sentinel_t<V> end_ = sentinel_t<V>(); // exposition only

        public:
            sentinel() = default;
            constexpr explicit sentinel(filter_view& parent);

            constexpr sentinel_t<V> base() const;

            friend constexpr bool operator==(const iterator& x, const sentinel& y);
        }
    }

    constexpr explicit sentinel(filter_view& parent);
1
Effects: Initializes end_ with ranges::end(parent.base_).

constexpr sentinel_t<V> base() const;
2
Effects: Equivalent to: return end_;

friend constexpr bool operator==(const iterator& x, const sentinel& y);
3
Effects: Equivalent to: return x.current_ == y.end_;

26.7.9 Transform view

26.7.9.1 Overview

transform_view presents a view of an underlying sequence after applying a transformation function to each element.
1
The name views::transform denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::transform(E, F) is expression-equivalent to transform_view(E, F).
3

[Example 1:

```cpp
vector<int> is{ 0, 1, 2, 3, 4 };
auto squares = views::transform(is, [] (int i) { return i * i; });
for (int i : squares)
    cout << i << ' '; // prints 0 1 4 9 16
```
—end example]

26.7.9.2 Class template transform_view
namespace std::ranges {
    template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
    regular_invocable<F&, range_reference_t<V> &&
    can_reference<invoke_result_t<F&, range_reference_t<V>>>  
    class transform_view : public view_interface<transform_view<V, F>> {
        private:
            // 26.7.9.3, class template transform_view::::iterator
            template<bool> struct iterator; // exposition only

            // 26.7.9.4, class template transform_view::::sentinel
            template<bool> struct sentinel; // exposition only

        V base_ = V(); // exposition only
        movable-box<F> fun_; // exposition only

        public:
            transform_view() requires default_initializable<V> && default_initializable<F> = default;
            constexpr explicit transform_view(V base, F fun);

            constexpr V base() const & requires copy_constructible<V> { return base_; }  
            constexpr V base() && { return std::move(base_); }  

            constexpr iterator<false> begin();  
            constexpr iterator<true> begin() const requires range<const V> &&
            regular_invocable<const F&, range_reference_t<const V>>;

            constexpr sentinel<false> end();  
            constexpr sentinel<false> end() const requires common_range<V> &&
            regular_invocable<const F&, range_reference_t<const V>>;

            constexpr sentinel<true> end() const requires common_range<const V> &&
            regular_invocable<const F&, range_reference_t<const V>>;

            constexpr auto size() requires sized_range<V> { return ranges::size(base_); }  
            constexpr auto size() const requires sized_range<const V>  
            { return ranges::size(base_); }  
    };

    template<class R, class F>
    transform_view(R&&, F) -> transform_view<views::all_t<R>, F>;
}

constexpr explicit transform_view(V base, F fun);  

1. Effects: Initializes base_ with std::move(base) and fun_ with std::move(fun).

constexpr iterator<false> begin();

2. Effects: Equivalent to:
   return iterator<false>{{*this, ranges::begin(base_)};

constexpr iterator<true> begin() const
   requires range<const V> &&
   regular_invocable<const F&, range_reference_t<const V>>;

3. Effects: Equivalent to:
   return iterator<true>{{*this, ranges::begin(base_)};

constexpr sentinel<false> end();

4. Effects: Equivalent to:
   return sentinel<false>{ranges::end(base_)};

§ 26.7.9.2 1201
constexpr iterator<false> end() requires common_range<V>;  

**Effects:** Equivalent to:

```
return iterator<false>(*this, ranges::end(base_));
```

constexpr sentinel<true> end() const 
requires range<const V> &
regular_invocable<const F&, range_reference_t<const V>>;

**Effects:** Equivalent to:

```
return sentinel<true>(ranges::end(base_));
```

constexpr iterator<true> end() const 
requires common_range<const V> &
regular_invocable<const F&, range_reference_t<const V>>;

**Effects:** Equivalent to:

```
return iterator<true>(*this, ranges::end(base_));
```

### 26.7.9.3 Class template `transform_view::iterator` [range.transform.iterator]

```cpp
namespace std::ranges {
    template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
    regular_invocable<F&, range_reference_t<V>> &&
    can_reference<invoke_result_t<F&, range_reference_t<V>>> 
    template<bool Const>
    class transform_view<V, F>::iterator {
        private:
            using Parent = maybe-const<Const, transform_view>;     // exposition only
            using Base = maybe-const<Const, V>;                     // exposition only
            iterator_t<Base> current_ = iterator_t<Base>();          // exposition only
            Parent* parent_ = nullptr;                                // exposition only

        public:
            using iterator_concept = see below;                      // not always present
            using iterator_category = see below;                     // not always present
            using value_type =
                remove_cvref_t<invoke_result_t<
                    maybe-const<Const, F&,
                    range_reference_t<Base>>>;
            using difference_type = range_difference_t<Base>;

            iterator() requires default_initializable<iterator_t<Base>> = default;
            constexpr iterator(Parent& parent, iterator_t<Base> current);
            constexpr iterator(iterator<false> i)
                requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
            constexpr const iterator_t<Base>& base() const & noexcept;
            constexpr iterator_t<Base>& base() &&;
            constexpr decltype(auto) operator*() const
                noexcept(noexcept(invoke(*parent_->fun_, *current_))) {
                    return invoke(*parent_->fun_, *current_);
                }
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator& operator++(int) requires forward_range<Base>;

            constexpr iterator& operator--() requires bidirectional_range<Base>;
            constexpr iterator& operator--(int) requires bidirectional_range<Base>;

            constexpr iterator& operator+=(difference_type n)
                requires random_access_range<Base>;
            constexpr iterator& operator+=(difference_type n)
                requires random_access_range<Base>;
```
constexpr decltype(auto) operator[](difference_type n) const
requires random_access_range<Base> {
    return invoke(*parent_->fun_, current_[n]);
}

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires equality_comparable<iterator_t<Base>>;

friend constexpr bool operator<(const iterator& x, const iterator& y)
requires random_access_range<Base>;

friend constexpr bool operator>(const iterator& x, const iterator& y)
requires random_access_range<Base>;

friend constexpr bool operator<=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

friend constexpr bool operator>=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

26.7.10 Take view [range.take]

26.7.10.1 Overview [range.take.overview]

take_view produces a view of the first \( N \) elements from another view, or all the elements if the adapted view contains fewer than \( N \).

The name `views::take` denotes a range adaptor object (26.7.2). Let \( E \) and \( F \) be expressions, let \( T \) be `remove_cvref_t<decltype(E)>`, and let \( B \) be `range_difference_t<decltype(E)>`. If `decltype(F)` does not model `convertible_to<D>`, `views::take(E, F)` is ill-formed. Otherwise, the expression `views::take(E, F)` is expression-equivalent to:

1. **(2.1)** If \( T \) is a specialization of `empty_view` (26.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of \( E \) and \( F \) are indeterminately sequenced.
2. **(2.2)** Otherwise, if \( T \) models `random_access_range` and `sized_range` and is a specialization of `span` (24.7.2.2), `basic_string_view` (23.3), or `subrange` (26.5.4), then `U(ranges::begin(E), ranges::begin(E) + std::min<D>(ranges::distance(E), F))`, except that \( E \) is evaluated only once, where \( U \) is a type determined as follows:
   1. **(2.2.1)** if \( T \) is a specialization of `span`, then \( U \) is `span<typename T::element_type>`;
   2. **(2.2.2)** otherwise, if \( T \) is a specialization of `basic_string_view`, then \( U \) is \( T \); 
   3. **(2.2.3)** otherwise, \( T \) is a specialization of `subrange`, and \( U \) is `subrange<iterator_t<T>>`;
   4. **(2.3)** otherwise, if \( T \) is a specialization of `iota_view` (26.6.4.2) that models `random_access_range` and `sized_range`, then `iota_view(ranges::begin(E), *(ranges::begin(E) + std::min<D>(ranges::distance(E), F)))`, except that \( E \) is evaluated only once.
5. **(2.4)** Otherwise, if \( T \) is a specialization of `repeat_view` (26.6.5.2):
   1. **(2.4.1)** if \( T \) models `sized_range`, then `views::repeat(*E.value_, std::min<D>(ranges::distance(E), F))` except that \( E \) is evaluated only once; 
   2. **(2.4.2)** otherwise, `views::repeat(*E.value_, static_cast<D>(F))`.
6. **(2.5)** Otherwise, `take_view(E, F)`.

Example 1:

```cpp
vector<int> is{0,1,2,3,4,5,6,7,8,9};
for (int i : is | views::take(5))
    cout << i << ' '; // prints 0 1 2 3 4
```
26.7.10.2 Class template take_view

```cpp
namespace std::ranges {
    template<class V>
    class take_view : public view_interface<take_view<V>> {
    private:
        V base_ = V(); // exposition only
        range_difference_t<V> count_ = 0; // exposition only

26.7.12 Drop view [range.drop]

26.7.12.1 Overview [range.drop.overview]

drop_view produces a view excluding the first \(N\) elements from another view, or an empty range if the adapted view contains fewer than \(N\) elements.

The name views::drop denotes a range adaptor object (26.7.2). Let \(E\) and \(F\) be expressions, let \(T\) be remove_cvref_t<decltype(E)>, and let \(D\) be range_difference_t<decltype(E)>. If decltype((F)) does not model convertible_to<D>, views::drop(E, F) is ill-formed. Otherwise, the expression views::drop(E, F) is expression-equivalent to:

1. If \(T\) is a specialization of empty_view (26.6.2.2), then ((void)F, decay-copy(E)), except that the evaluations of \(E\) and \(F\) are indeterminately sequenced.

2. Otherwise, if \(T\) models random_access_range and sized_range and is
   1. a specialization of span (24.7.2.2),
   2. a specialization of basic_string_view (23.3),
   3. a specialization of iota_view (26.6.4.2), or
   4. a specialization of subrange (26.5.4) where \(T::StoreSize\) is false, then \(U\langle\text{ranges::begin}(E) + \text{std::min}\langle\text{D}\rangle(\text{ranges::distance}(E), F), \text{ranges::end}(E)\rangle\), except that \(E\) is evaluated only once, where \(U\) is span<typename T::element_type> if \(T\) is a specialization of span and \(T\) otherwise.

3. Otherwise, if \(T\) is a specialization of subrange (26.5.4) that models random_access_range and sized_range, then \(T\langle\text{ranges::begin}(E) + \text{std::min}\langle\text{D}\rangle(\text{ranges::distance}(E), F), \text{ranges::end}(E)\rangle, \text{to-unsigned-like}(\text{ranges::distance}(E) - \text{std::min}\langle\text{D}\rangle(\text{ranges::distance}(E), F))\rangle\), except that \(E\) and \(F\) are each evaluated only once.

4. Otherwise, if \(T\) is a specialization of repeat_view (26.6.5.2):
   1. if \(T\) models sized_range, then views::repeat(*E.value_, ranges::distance(E) - std::min\langle\text{D}\rangle(\text{ranges::distance}(E), F)) except that \(E\) is evaluated only once;
   2. otherwise, ((void)F, decay-copy(E)), except that the evaluations of \(E\) and \(F\) are indeterminately sequenced.

5. Otherwise, drop_view(E, F).

[Example 1:] auto ints = views::iota(0) | views::take(10); for (auto i : ints | views::drop(5)) { cout << i << ' '; // prints 5 6 7 8 9 }

—end example—

26.7.12.2 Class template drop_view [range.drop.view]

namespace std::ranges {

template<br>

class drop_view : public view_interface<drop_view<V>> { public:

drop_view() requires default_initializable<V> = default;

conestexpr explicit drop_view(V base, range_difference_t<V> count);

constexpr V base() const & requires copy_constructible<V> { return base_; } constexpr V base() & { return std::move(base_); }

}
constexpr auto begin()
requires (!simple-view<V> &&
    random_access_range<const V> && sized_range<const V>));
constexpr auto begin() const
requires random_access_range<const V> && sized_range<const V>;

constexpr auto end() requires (!simple-view<V>)
{ return ranges::end(base_); }
constexpr auto end() const requires range<const V>
{ return ranges::end(base_); }

constexpr auto size() requires sized_range<V> {
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}
constexpr auto size() const requires sized_range<const V> {
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}

private:
V base_ = V();                                                           // exposition only
range_difference_t<V> count_ = 0;                                       // exposition only
};

template<class R>
drop_view(R&&, range_difference_t<R>) -> drop_view<views::all_t<R>>;

customexpr explicit drop_view(V base, range_difference_t<V> count);

Preconditions: count >= 0 is true.
Effects: Initializes base_ with std::move(base) and count_ with count.

constexpr auto begin()
requires (!simple-view<V> &&
    random_access_range<const V> && sized_range<const V>));
constexpr auto begin() const
requires random_access_range<const V> && sized_range<const V>;

Returns: ranges::next(ranges::begin(base_), count_, ranges::end(base_)).
Remarks: In order to provide the amortized constant-time complexity required by the range concept when drop_view models forward_range, the first overload caches the result within the drop_view for use on subsequent calls.

[Note 1: Without this, applying a reverse_view over a drop_view would have quadratic iteration complexity. —end note]

26.7.13 Drop while view
26.7.13.1 Overview

Given a unary predicate pred and a view r, drop_while_view produces a view of the range [ranges::find_if_not(r, pred), ranges::end(r)].

The name views::drop_while denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::drop_while(E, F) is expression-equivalent to drop_while_view(E, F).

[Example 1:
constexpr auto source = " 	 	 	 hello there"sv;
auto is_invisible = [](const auto x) { return x == ' ' || x == '\'t'; };
auto skip_ws = views::drop_while(source, is_invisible);]
for (auto c : skip_ws) {
    cout << c; // prints hello there with no leading space
}
—end example]

26.7.13.2 Class template `drop_while_view`

```cpp
namespace std::ranges {
    template<view V, class Pred>
    requires input_range<V> && is_object_v<Pred> &&
    indirect_unary_predicate<const Pred, iterator_t<V>>
    class drop_while_view : public view_interface<drop_while_view<V, Pred>> {
public:
    drop_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
    constexpr explicit drop_while_view(V base, Pred pred);
    constexpr V base() const & requires copy_constructible<V> { return
std::move(base_); }
    constexpr V base() && { return std::move(base_); }
    constexpr const Pred& pred() const;
    constexpr auto begin();
    constexpr auto end() { return ranges::end(base_); }
private:
    V base_ = V(); // exposition only
    movable-box<Pred> pred_; // exposition only
};

template<class R, class Pred>
drop_while_view(R&&, Pred) -> drop_while_view<views::all_t<R>, Pred>;
```

```cpp
constexpr explicit drop_while_view(V base, Pred pred);

Effects: Initializes `base_` with `std::move(base)` and `pred_` with `std::move(pred)`.

constexpr const Pred& pred() const;

Effects: Equivalent to: `return *pred_`;

constexpr auto begin();

Preconditions: `pred_.has_value()` is true.

Returns: `ranges::find_if_not(base_, cref(*pred_))`.

Remarks: In order to provide the amortized constant-time complexity required by the range concept when `drop_while_view` models `forward_range`, the first call caches the result within the `drop_while_view` for use on subsequent calls.

[Note 1: Without this, applying a `reverse_view` over a `drop_while_view` would have quadratic iteration complexity. — end note]

26.7.14 Join view

26.7.14.1 Overview

`join_view` flattens a view of ranges into a view.

The name `views::join` denotes a range adaptor object (26.7.2). Given a subexpression `E`, the expression `views::join(E)` is expression-equivalent to `join_view<views::all_t<decltype((E))>>{E}`.

[Example 1:
    vector<string> ss{"hello", " ", "world", "!"};
    for (char ch : ss | views::join)
        cout << ch; // prints hello world!
—end example]
26.7.14.2  Class template join_view

namespace std::ranges {

    noexcept(noexcept(ranges::iter_swap(*x.
    inner_, *y.
    inner_))) requires indirectly_swappable<InnerIter>;  
}

1 iterator::iterator_concept is defined as follows:

(1.1) — If ref-is-glvalue is true, Base models bidirectional_range, and range_reference_t<Base> models both bidirectional_range and common_range, then iterator_concept denotes bidirectional_iterator_tag.  

(1.2) — Otherwise, if ref-is-glvalue is true and Base and range_reference_t<Base> each model forward_range, then iterator_concept denotes forward_iterator_tag.  

(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.  

2 The member typedef-name iterator_category is defined if and only if ref-is-glvalue is true, Base models forward_range, and range_reference_t<Base> models forward_range. In that case, iterator::iterator_category is defined as follows:

(2.1) — Let OUTERC denote iterator_traits<iterator_t<Base>>::iterator_category, and let INNERC denote iterator_traits<iterator_t<range_reference_t<Base>>>::iterator_category.  

(2.2) — If OUTERC and INNERC each model derived_from<bidirectional_iterator_tag> and range_reference_t<Base> models common_range, iterator_category denotes bidirectional_iterator_tag.  

(2.3) — Otherwise, if OUTERC and INNERC each model derived_from<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.  

(2.4) — Otherwise, iterator_category denotes input_iterator_tag.  

3 iterator::difference_type denotes the type:
    common_type_t<
        range_difference_t<Base>,
        range_difference_t<range_reference_t<Base>>>

4 join_view iterators use the satisfy function to skip over empty inner ranges.

constexpr OuterIter outer();
constexpr const OuterIter& outer() const;

Returns: outer_ if Base models forward_range; otherwise, *parent_->outer_.

§ 26.7.14.3
constexpr void satisfy();

Effects: Equivalent to:

```cpp
default
auto update_inner = [this](const iterator_t<Base>& x) -> auto&& {
    if constexpr (ref-is-glvalue)  // x is a reference
        return *x;
    else
        return parent_->inner_.emplace-deref(x);
};
```

```cpp
for (; outer() != ranges::end(parent_->base_); ++outer()) {
    auto&& inner = update_inner(outer());
    inner_ = ranges::begin(inner);
    if (*inner_ != ranges::end(inner))
        return;
}
```

```cpp
if constexpr (ref-is-glvalue)
    inner_.reset();
```

```cpp
constexpr iterator(Parent& parent, OuterIter outer)
requires forward_range<Base>;
```

Effects: Initializes outer_ with std::move(outer) and parent_ with addressof(parent); then calls satisfy().

```cpp
explicit iterator(Parent& parent)
requires (!forward_range<Base>);
```

Effects: Initializes parent_ with addressof(parent); then calls satisfy().

```cpp
iterator(iterator<!Const> i)
requires Const &&
    convertible_to<iterator_t<Base>, OuterIter> &&
    convertible_to<iterator_t<InnerRng>, InnerIter>;
```

Effects: Initializes outer_ with std::move(i.outer_), inner_ with std::move(i.inner_), and parent_ with i.parent_.

[Note 1: Const can only be true when Base models forward_range. —end note]

```cpp
InnerIter operator->() const
requires has-arrow<InnerIter> && copyable<InnerIter>;
```

Effects: Equivalent to: return *inner_

```cpp
iterator& operator++();
```

Effects: Equivalent to: ++*this.

```cpp
iterator operator++(int)
requires ref-is-glvalue && forward_range<Base> &&
    forward_range<range_reference_t<Base>>;
```

Effects: Equivalent to: ++*this.

constexpr void operator++(int);

Effects: Equivalent to: +++this.

§ 26.7.14.3
16 Effects: Equivalent to:
   
   if (outer_ == ranges::end(parent_->base_))
      inner_ = ranges::end(as-lvalue(*--outer_));
   while (*inner_ == ranges::begin(as-lvalue(*outer_)))
      *inner_ = ranges::end(as-lvalue(*--outer_));

```

### § 26.7.15.3 1221
friend constexpr bool operator==(const iterator& x, const iterator& y)
    requires ref-is-glvalue && forward_range<Base> && equality_comparable<InnerIter>;
friend constexpr decltype(auto) iter_move(const iterator& x) {
    using rvalue_reference = common_reference_t<
        iter_rvalue_reference_t<InnerIter>,
        iter_rvalue_reference_t<PatternIter>>;
    return visit<rvalue_reference>(ranges::iter_move, x.inner_it_);
}
friend constexpr void iter_swap(const iterator& x, const iterator& y)
    requires indirectly_swappable<InnerIter, PatternIter> {
    visit(ranges::iter_swap, x.inner_it_, y.inner_it_);
}

1 iterator::iterator_concept is defined as follows:
(1.1) — If ref-is-glvalue is true, Base models bidirectional_range, and InnerBase and PatternBase each model bidirectional_common, then iterator_concept denotes bidirectional_iterator_tag.
(1.2) — Otherwise, if ref-is-glvalue is true and Base and InnerBase each model forward_range, then iterator_concept denotes forward_iterator_tag.
(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member typedef-name iterator_category is defined if and only if ref-is-glvalue is true, and Base and InnerBase each model forward_range. In that case, iterator::iterator_category is defined as follows:
(2.1) — Let OUTERC denote iterator_traits<OuterIter>::iterator_category, let INNERC denote iterator_traits<InnerIter>::iterator_category, and let PATTERNC denote iterator_traits<PatternIter>::iterator_category.
(2.2) — If
        is_reference_v<
            common_reference_t<
                iter_reference_t<InnerIter>,
                iter_reference_t<PatternIter>>
    is false, iterator_category denotes input_iterator_tag.
(2.3) — Otherwise, if OUTERC, INNERC, and PATTERNC each model derived_from<bidirectional_iterator_category> and InnerBase and PatternBase each model common_range, iterator_category denotes bidirectional_iterator_tag.
(2.4) — Otherwise, if OUTERC, INNERC, and PATTERNC each model derived_from<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.
(2.5) — Otherwise, iterator_category denotes input_iterator_tag.

3 iterator::value_type denotes the type:
    common_type_t<
        iter_value_t<InnerIter>,
        iter_value_t<PatternIter>>

4 iterator::difference_type denotes the type:
    common_type_t<
        iter_difference_t<OuterIter>,
        iter_difference_t<InnerIter>,
        iter_difference_t<PatternIter>>

constexpr OuterIter& outer();
constexpr const OuterIter& outer() const;

Returns: outer_.it_ if Base models forward_range; otherwise, *parent_->outer_.it_.

constexpr auto& update-inner();

Effects: Equivalent to:
        if constexpr (ref-is-glvalue)
            return as-lvalue(*outer());
© ISO/IEC

…

else
    return parent_->inner_.emplace_deref(outer());

constexpr auto& get-inner();

Effects: Equivalent to:

if constexpr (ref-is-glvalue)
    return as-lvalue(*outer());
else
    return *parent_->inner_;

constexpr void satisfy();

Effects: Equivalent to:

while (true) {
    if (inner_it_.index() == 0) {
        if (std::get<0>(inner_it_) != ranges::end(parent_->pattern_))
            break;

}

26.7.16 Lazy split view

26.7.16.1 Overview

lazy_split_view takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

The name views::lazy_split denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::lazy_split(E, F) is expression-equivalent to lazy_split_view(E, F).

[Example 1:
    string str("the quick brown fox");
    for (auto word : str | views::lazy_split(' ')) {
        for (char ch : word)
            cout << ch;
        cout << '*';
    }
    // The above prints the*quick*brown*fox*
    —end example]

    constexpr explicit outer_iterator(Parent& parent)
      requires (forward_range<Base>);
    constexpr outer_iterator(Parent& parent, iterator_t<Base> current)
      requires forward_range<Base>;
    constexpr outer_iterator(outer_iterator<!Const> i)
      requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

    constexpr value_type operator*() const;
    constexpr outer_iterator& operator++();
    constexpr decltype(auto) operator++(int) {
      if constexpr (forward_range<Base>) {
        auto tmp = *this;
        ++*this;
        return tmp;
      } else
        ++*this;
    }
  }
} // std::ranges
friend constexpr bool operator==(const outer_iterator& x, const outer_iterator& y)  
    requires forward_range<Base>;

friend constexpr bool operator==(const outer_iterator& x, default_sentinel_t);

Many of the specifications in 26.7.16 refer to the notional member current of outer_iterator. current is equivalent to current_, if V models forward_range, and *parent_->current_ otherwise.

constexpr explicit outer_iterator(Parent& parent)  
    requires (!forward_range<Base>);

Effects: Initializes parent_ with addressof(parent).

constexpr outer_iterator(Parent& parent, iterator_t<Base> current)  
    requires forward_range<Base>;

Effects: Initializes parent_ with addressof(parent) and current_ with std::move(current).

constexpr outer_iterator<!Const> i)  
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

Effects: Initializes parent_ with i, parent_, current_ with std::move(i.current_), and trailing_empty_ with i.trailing_empty_.

constexpr value_type operator*() const;

Effects: Equivalent to: return value_type{*this};

constexpr outer_iterator& operator++();

Effects: Equivalent to:

    const auto end = ranges::end(parent_->base_);  
    if (current == end) {  
        trailing_empty_ = false;  
        return *this;  
    }  
    const auto [pbegin, pend] = subrange(parent_->pattern_);  
    if (pbegin == pend) ++current;  
    else if constexpr (tiny-range<Pattern>) {  
        current = ranges::find(std::move(current), end, *pbegin);  
        if (current != end) {  
            ++current;  
            if (current == end)  
                trailing_empty_ = true;  
        }  
    }  
    else {  
        do {  
            auto [b, p] = ranges::mismatch(current, end, pbegin, pend);  
            if (p == pend) {  
                current = b;  
                if (current == end)  
                    trailing_empty_ = true;  
                break;  
                // The pattern matched; skip it  
            }  
        } while (++current != end);  
    }  
return *this;

friend constexpr bool operator==(const outer_iterator& x, const outer_iterator& y)  
    requires forward_range<Base>;

Effects: Equivalent to:

    return x.current_ == y.current_ && x.trailing_empty_ == y.trailing_empty_;

§ 26.7.16.3
friend constexpr bool operator==(const outer_iterator x, default_sentinel_t);  

Effects: Equivalent to:

```
return x.current == ranges::end(x.parent->base_) && !x.trailing_empty_;  
```

### 26.7.16.4 Class lazy_split_view::outer_iterator::value_type

```
namespace std::ranges {
    template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
    (forward_range<V> || tiny-range<Pattern>)
    template<bool Const>
    struct lazy_split_view<V, Pattern>::outer_iterator<Const>::value_type
        : view_interface<value_type> {

    private:
        outer_iterator i_ = outer_iterator(); // exposition only

    public:
        value_type() = default;
        constexpr explicit value_type(outer_iterator i);
        constexpr inner_iterator<Const> begin() const;
        constexpr default_sentinel_t end() const noexcept;
    }
}
```

1. **Effects**: Initializes i_ with std::move(i).
2. **Effects**: Equivalent to: return inner_iterator<Const>{i_};
3. **Effects**: Equivalent to: return default_sentinel;

### 26.7.16.5 Class template lazy_split_view::inner_iterator

```
namespace std::ranges {
    template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
    (forward_range<V> || tiny-range<Pattern>)
    template<bool Const>
    struct lazy_split_view<V, Pattern>::inner_iterator {

    private:
        using Base = maybe-const<Const, V>; // exposition only
        outer_iterator<Const> i_ = outer_iterator<Const>(); // exposition only
        bool incremented_ = false; // exposition only

    public:
        using iterator_concept = typename outer_iterator<Const>::iterator_concept;
        using iterator_category = see below; // present only if Base
        using value_type = range_value_t<Base>;
        using difference_type = range_difference_t<Base>;

        inner_iterator() = default;
        constexpr explicit inner_iterator(outer_iterator<Const> i);

        constexpr const iterator_t<Base>& base() const & noexcept;
        constexpr iterator_t<Base> base() && requires forward_range<V>;

        constexpr decltype(auto) operator*() const { return *i_.current; }
    }
}
```
constexpr inner_iterator& operator++();
constexpr decltype(auto) operator++(int) {
    if constexpr (forward_range<Base>) {
        auto tmp = *this;
        ++*this;
        return tmp;
    } else
        ++*this;
}

friend constexpr bool operator==(const inner_iterator& x, const inner_iterator& y) requires forward_range<Base>;
friend constexpr bool operator==(const inner_iterator& x, default_sentinel_t);

friend constexpr decltype(auto) iter_move(const inner_iterator& i) noexcept(noexcept(ranges::iter_move(i.i_.current))) {
    return ranges::iter_move(i.i_.current);
}

friend constexpr void iter_swap(const inner_iterator& x, const inner_iterator& y) noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current))) requires indirectly_swappable<iterator_t<Base>>;

1 If Base does not model forward_range there is no member iterator_category. Otherwise, the typedef-name iterator_category denotes:

1.1 forward_iterator_tag if iterator_traits<iterator_t<Base>>::iterator_category models derived_from<forward_iterator_tag>;
1.2 otherwise, iterator_traits<iterator_t<Base>>::iterator_category.

constexpr explicit inner_iterator(outer_iterator<Const> i);

Effects: Initializes i_ with std::move(i).

constexpr const iterator_t<Base>& base() const & noexcept;

Effects: Equivalent to: return i_.current;

constexpr iterator_t<Base> base() && requires forward_range<V>;

Effects: Equivalent to: return std::move(i_.current);

constexpr inner_iterator& operator++();

Effects: Equivalent to:

incremented_ = true;
if constexpr (!forward_range<Base>) {
    if constexpr (Pattern::size() == 0) {
        return *this;
    }
} +++i_.current;
return *this;

friend constexpr bool operator==(const inner_iterator& x, const inner_iterator& y) requires forward_range<Base>;

Effects: Equivalent to: return x.i_.current == y.i_.current;

friend constexpr bool operator==(const inner_iterator& x, default_sentinel_t);

Effects: Equivalent to:

auto [pcur, pend] = subrange{x.i_.parent_->pattern_};
auto end = ranges::end(x.i_.parent_->base_);
if constexpr (tiny-range<Pattern>) {
    const auto & cur = x.i_.current;
    if (cur == end) return true;
    if (pcur == pend) return x.incremented;
    return *cur == *pcur;
} else {
    auto cur = x.i_.current;
    if (cur == end) return true;
    if (pcur == pend) return x.incremented;
    do {
        if (*cur != *pcur) return false;
        if (++pcur == pend) return true;
    } while (++cur != end);
    return false;
}

friend constexpr void iter_swap(const inner_iterator& x, const inner_iterator& y)
    noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
    requires indirectly_swappable<iterator_t<Base>>;

Effects: Equivalent to ranges::iter_swap(x.i_.current, y.i_.current).

26.7.17 Split view

26.7.17.1 Overview

split_view takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

The name views::split denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::split(E, F) is expression-equivalent to split_view(E, F).

[Example 1:

string str = "the quick brown fox");
for (auto word : views::split(str, ' ')) {
    cout << string_view(word) << ' '*;
} // The above prints the*quick*brown*fox*
—end example]

26.7.17.2 Class template split_view

namespace std::ranges {
    template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
        indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
    class split_view : public view_interface<split_view<V, Pattern>> {
        private:
            V base_ = V(); // exposition only
            Pattern pattern_ = Pattern(); // exposition only

            // 26.7.17.3, class split_view::iterator
            struct iterator;
            // exposition only

            // 26.7.17.4, class split_view::sentinel
            struct sentinel;
            // exposition only

        public:
            split_view() requires default_initializable<V> && default_initializable<Pattern> = default;
            constexpr explicit split_view(V base, Pattern pattern);

            template<forward_range R>
            requires constructible_from<V, views::all_t<R>> &&
                constructible_from<Pattern, single_view<range_value_t<R>>>
            constexpr explicit split_view(R&& r, range_value_t<R> e);
constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr iterator begin();
constexpr auto end() {
  if constexpr (common_range<V>) {
    return iterator{*this, ranges::end(base_), {}};
  } else {
    return sentinel{*this};
  }
}

constexpr subrange<iterator_t<V>> find-next(iterator_t<V>); // exposition only
};

template<class R, class P>
split_view(R&&, P&&) -> split_view<views::all_t<R>, views::all_t<P>>;

template<forward_range R>
split_view(R&&, range_value_t<R>)
  -> split_view<views::all_t<R>, single_view<range_value_t<R>>>;

constexpr explicit split_view(V base, Pattern pattern);
1 Effects: Initializes base_ with std::move(base), and pattern_ with std::move(pattern).

template<forward_range R>
requires constructible_from<V, views::all_t<R>> &&
constructible_from<Pattern, single_view<range_value_t<R>>>
constexpr explicit split_view(R&& r, range_value_t<R> e);
2 Effects: Initializes base_ with views::all(std::forward<R>(r)), and pattern_ with views::
  single(std::move(e)).

constexpr iterator begin();
3 Returns: {*this, ranges::begin(base_), find-next(ranges::begin(base_))}.

Remarks: In order to provide the amortized constant time complexity required by the range concept,
this function caches the result within the split_view for use on subsequent calls.

constexpr subrange<iterator_t<V>> find-next(iterator_t<V> it);
5 Effects: Equivalent to:

    auto [b, e] = ranges::search(subrange(it, ranges::end(base_)), pattern_);
    if (b != ranges::end(base_) && ranges::empty(pattern_)) {
      ++b;
      ++e;
    }
    return {b, e};

26.7.17.3 Class split_view::iterator

namespace std::ranges {
  template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
class split_view<V, Pattern>::iterator {
  private:
    split_view* parent_ = nullptr;  // exposition only
    iterator_t<V> cur_ = iterator_t<V>();  // exposition only
    subrange<iterator_t<V>> next_ = subrange<iterator_t<V>>();  // exposition only
    bool trailing_empty_ = false;  // exposition only

public:
  using iterator_concept = forward_iterator_tag;
  using iterator_category = input_iterator_tag;
  using value_type = subrange<iterator_t<V>>;
  using difference_type = range_difference_t<V>;

  iterator() = default;
  constexpr iterator(split_view& parent, iterator_t<V> current, subrange<iterator_t<V>> next);
  constexpr iterator_t<V> base() const;
  constexpr value_type operator*() const;
  constexpr iterator& operator++();
  constexpr iterator operator++(int);

  friend constexpr bool operator==(const iterator& x, const iterator& y);
};

constexpr iterator(split_view& parent, iterator_t<V> current, subrange<iterator_t<V>> next);
  Effects: Initializes parent_ with addressof(parent), cur_ with std::move(current), and next_ with std::move(next).

constexpr iterator_t<V> base() const;
  Effects: Equivalent to: return cur_;

constexpr value_type operator*() const;
  Effects: Equivalent to: return {cur_, next_.begin()};

constexpr iterator& operator++();
  Effects: Equivalent to:
  cur_ = next_.begin();
  if (cur_ != ranges::end(parent_->base_)) {
    cur_ = next_.end();
    if (cur_ == ranges::end(parent_->base_)) {
      trailing_empty_ = true;
      next_ = {cur_, cur_};
    } else {
      next_ = parent_->find-next(cur_);
    }
  } else {
    trailing_empty_ = false;
  }
  return *this;

constexpr iterator operator++(int);
  Effects: Equivalent to:
  auto tmp = *this;
  ++*this;
  return tmp;

friend constexpr bool operator==(const iterator& x, const iterator& y);
  Effects: Equivalent to:
  return x.cur_ == y.cur_ && x.trailing_empty_ == y.trailing_empty_;
private:
    sentinel_t<V> end_ = sentinel_t<V>(); // exposition only

public:
    sentinel() = default;
    constexpr explicit sentinel(spinl_view& parent);

    friend constexpr bool operator==(const iterator& x, const sentinel& y);
    
constexpr explicit sentinel(spinl_view& parent);  

    Effects: Initializes end_ with ranges::end(parent.base_).

friend constexpr bool operator==(const iterator& x, const sentinel& y);

    Effects: Equivalent to: return x.cur_ == y.end_ && !x.trailing_empty_;  

26.7.18 Counted view [range.counted]

1 A counted view presents a view of the elements of the counted range (25.3.1) \(i + [0, n]\) for an iterator \(i\) and non-negative integer \(n\).

2 The name \(\text{views::counted}\) denotes a customization point object (16.3.3.3.5). Let \(E\) and \(F\) be expressions, let \(T\) be \(\text{decay_t}\langle\text{decltype}\langle(E)\rangle\rangle\), and let \(D\) be \(\text{iter_difference_t}\langle T\rangle\). If \(\text{decltype}\langle F\rangle\) does not model \(\text{convertible_to}\langle D\rangle\), \(\text{views::counted}(E, F)\) is ill-formed.

[Note 1: This case can result in substitution failure when \(\text{views::counted}(E, F)\) appears in the immediate context of a template instantiation. —end note]

Otherwise, \(\text{views::counted}(E, F)\) is expression-equivalent to:

(2.1) — If \(T\) models \(\text{contiguous_iterator}\), then span(to_address(E), static_cast<size_t>(static_cast<\langle D\rangle\langle F\rangle\rangle)).

(2.2) — Otherwise, if \(T\) models \(\text{random_access_iterator}\), then subrange(E, E + static_cast<\langle D\rangle\langle F\rangle\rangle), except that \(E\) is evaluated only once.

(2.3) — Otherwise, subrange(counted_iterator(E, F), default_sentinel).

26.7.19 Common view [range.common]

26.7.19.1 Overview [range.common.overview]

1 \(\text{common_view}\) takes a view which has different types for its iterator and sentinel and turns it into a view of the same elements with an iterator and sentinel of the same type.

[Note 1: \(\text{common_view}\) is useful for calling legacy algorithms that expect a range's iterator and sentinel types to be the same. —end note]

3 The name \(\text{views::common}\) denotes a range adaptor object (26.7.2). Given a subexpression \(E\), the expression \(\text{views::common}(E)\) is expression-equivalent to:

(3.1) — \(\text{views::all}(E)\), if \(\text{decltype}(E)\) models \(\text{common_range}\) and \(\text{views::all}(E)\) is a well-formed expression.

(3.2) — Otherwise, \(\text{common_view}(E)\).

[Example 1:

// Legacy algorithm:
    template<class ForwardIterator>
    size_t count(ForwardIterator first, ForwardIterator last);

    template<forward_range R>
    void my_algo(R&& r) {
        auto&& common = views::common(r);
        auto cnt = count(common.begin(), common.end());
        // ...
    }

—end example]
26.7.19.2 Class template common_view

namespace std::ranges {
    template<typename V>
    requires (!common_range<V> && copyable<iterator_t<V>>)
    class common_view : public view_interface<common_view<V>> {
private:
        V base_ = V();  // exposition only

public:
        common_view() requires default_initializable<V> = default;
        constexpr explicit common_view(V r);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin() {
        if constexpr (random_access_range<V> && sized_range<V>)
            return ranges::begin(base_);
        else
            return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::begin(base_));
    }

    constexpr auto begin() const requires range<const V> {
        if constexpr (random_access_range<const V> && sized_range<const V>)
            return ranges::begin(base_);
        else
            return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::begin(base_));
    }

    constexpr auto end() {
        if constexpr (random_access_range<V> && sized_range<V>)
            return ranges::begin(base_) + ranges::distance(base_);
        else
            return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::end(base_));
    }

    constexpr auto end() const requires range<const V> {
        if constexpr (random_access_range<const V> && sized_range<const V>)
            return ranges::begin(base_) + ranges::distance(base_);
        else
            return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::end(base_));
    }

    constexpr auto size() requires sized_range<V> {
        return ranges::size(base_);
    }
    constexpr auto size() const requires sized_range<const V> {
        return ranges::size(base_);
    }
};

    template<class R>
    common_view(R&&) -> common_view<views::all_t<R>>;

constexpr explicit common_view(V base);

Effects: Initializes base_ with std::move(base).
26.7.20 Reverse view

26.7.20.1 Overview

1 `reverse_view` takes a bidirectional view and produces another view that iterates the same elements in reverse order.

2 The name views::reverse denotes a range adaptor object (26.7.2). Given a subexpression E, the expression views::reverse(E) is expression-equivalent to:

- If the type of E is a (possibly cv-qualified) specialization of reverse_view, equivalent to E.base().
- Otherwise, if the type of E is cv subrange<reverse_iterator<I>, reverse_iterator<I>, K> for some iterator type I and value K of type subrange_kind,
  - if K is subrange_kind::sized, equivalent to:
    subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())
  - otherwise, equivalent to:
    subrange<I, I, K>(E.end().base(), E.begin().base())

- Otherwise, equivalent to reverse_view(E).

However, in either case E is evaluated only once.

3 [Example 1]:
vector<int> is {0,1,2,3,4};
for (int i : is | views::reverse)
  cout << i << ' '; // prints 4 3 2 1 0
— end example]

26.7.20.2 Class template reverse_view

namespace std::ranges {
  template<view V>
  requires bidirectional_range<V>
  class reverse_view : public view_interface<reverse_view<V>> {
    private:
      V base_ = V(); // exposition only

    public:
      reverse_view() requires default_initializable<V> = default;

      constexpr explicit reverse_view(V r);

      constexpr V base() const & requires copy_constructible<V> { return base_; }
      constexpr V base() && { return std::move(base_); }

      constexpr reverse_iterator<iterator_t<V>> begin();
      constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
      constexpr auto begin() const requires common_range<const V>;

      constexpr reverse_iterator<iterator_t<V>> end();
      constexpr auto end() const requires common_range<const V>;

      constexpr auto size() requires sized_range<V> {
        return ranges::size(base_);
      }

      constexpr auto size() const requires sized_range<const V> {
        return ranges::size(base_);
      }
  };

  template<class R>
  reverse_view(R&&) -> reverse_view<views::all_t<R>>;
}
constexpr explicit reverse_view(V base);

Effects: Initializes base_ with std::move(base).

constexpr reverse_iterator<iterator_t<V>> begin();

Returns:
make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))

Remarks: In order to provide the amortized constant time complexity required by the range concept, this function caches the result within the reverse_view for use on subsequent calls.

constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;
constexpr auto begin() const requires common_range<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::end(base_));

constexpr reverse_iterator<iterator_t<V>> end();
constexpr auto end() const requires common_range<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::begin(base_));

26.7.21 As const view

as_const_view presents a view of an underlying sequence as constant. That is, the elements of an as_const_view cannot be modified.

The name views::as_const denotes a range adaptor object (26.7.2). Let E be an expression, let T be decltype((E)), and let U be remove_cvref_t<T>. The expression views::as_const(E) is expression-equivalent to:

(2.1) — If views::all_t<T> models constant_range, then views::all(E).
(2.2) — Otherwise, if U denotes empty_view<X> for some type X, then auto(views::empty<const X>).
(2.3) — Otherwise, if U denotes span<X, Extent> for some type X and some extent Extent, then span<const X, Extent>(E).
(2.4) — Otherwise, if U denotes ref_view<X> for some type X and const X models constant_range, then ref_view(static_cast<const X&>(E.base())).
(2.5) — Otherwise, if E is an lvalue, const U models constant_range, and U does not model view, then ref_view(static_cast<const U&>(E)).
(2.6) — Otherwise, as_const_view(E).

[Example 1]
template<constant_range R>
void cant_touch_this(R&&);

vector<char> hammer = {'m', 'c'};
span<char> beat = hammer;
cant_touch_this(views::as_const(beat)); // will not modify the elements of hammer

— end example]

26.7.21.2 Class template as_const_view

namespace std::ranges {
    template<view V>
    requires input_range<V>
    class as_const_view : public view_interface<as_const_view<V>> {
        V base_ = V(); // exposition only

        public:

cconstexpr explicit as_const_view(V base);

Effects: Initializes base_ with std::move(base).

26.7.22 Elements view

26.7.22.1 Overview

`elements_view` takes a view of tuple-like values and a `size_t`, and produces a view with a value-type of the `N`th element of the adapted view’s value-type.

The name `views::elements<N>` denotes a range adaptor object (26.7.2). Given a subexpression `E` and constant expression `N`, the expression `views::elements<N>(E)` is expression-equivalent to `elements_view<views::all_t<decltype((E))>, N>{E}`.

[Example 1:]

```cpp
auto historical_figures = map{
    pair("Lovelace"sv, 1815),
    {"Turing"sv, 1912},
    {"Babbage"sv, 1791},
    {"Hamilton"sv, 1936}
};

auto names = historical_figures | views::elements<0>;
for (auto& name : names) {
    cout << name << ' ';
    // prints Babbage Hamilton Lovelace Turing
}

auto birth_years = historical_figures | views::elements<1>;
for (auto& born : birth_years) {
    cout << born << ' ';
    // prints 1936 1815 1912
}
```

—end example]

`keys_view` is an alias for `elements_view<R, 0>`, and is useful for extracting keys from associative containers.

[Example 2:]

```cpp
auto names = historical_figures | views::keys;
for (auto& name : names) {
    cout << name << ' ';
    // prints Babbage Hamilton Lovelace Turing
}
```

—end example]

`values_view` is an alias for `elements_view<R, 1>`, and is useful for extracting values from associative containers.

[Example 3:]

```cpp
auto is_even = [](const auto x) { return x % 2 == 0; };
cout << ranges::count_if(historical_figures | views::values, is_even); // prints 2
```

—end example]
26.7.22.2 Class template elements_view

26.7.23 Enumerate view [range.enumerate]

26.7.23.1 Overview [range.enumerate.overview]
enumerate_view is a view whose elements represent both the position and value from a sequence of elements.

The name std::views::enumerate denotes a range adaptor object (26.7.2). Given a subexpression E, the expression
views::enumerate(E) is expression-equivalent to enumerate_view<views::all_t<decltype((E))>>(E).

[Example 1:
    vector<int> vec{ 1, 2, 3 };
    for (auto [index, value] : views::enumerate(vec))
        cout << index << "::" << value << ' ' ;  // prints 0:1 1:2 2:3
    —end example]

26.7.23.2 Class template enumerate_view [range.enumerate.view]

            }
        }
}
```

§ 26.7.24.2 1249
Two `zip_view` objects have the same underlying sequence if and only if the corresponding elements of `views` are equal (18.2) and have the same underlying sequence.

[Note 1: In particular, comparison of iterators obtained from `zip_view` objects that do not have the same underlying sequence is not required to produce meaningful results (25.3.4.11). — end note]
constexpr iterator& operator+=(difference_type x)  
requires all-random-access<Const, Views...>;
constexpr iterator operator-=(difference_type x)  
requires all-random-access<Const, Views...>;
constexpr auto operator[](difference_type n) const  
requires all-random-access<Const, Views...>;

friend constexpr bool operator==(const iterator& x, const iterator& y)  
requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);
friend constexpr auto operator<=>(const iterator& x, const iterator& y)  
requires all-random-access<Const, Views...>;
friend constexpr iterator operator+(const iterator& i, difference_type n)  
requires all-random-access<Const, Views...>;
friend constexpr iterator operator+(difference_type n, const iterator& i)  
requires all-random-access<Const, Views...>;
friend constexpr iterator operator-(const iterator& i, difference_type n)  
requires all-random-access<Const, Views...>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)  
requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>, iterator_t<maybe-const<Const, Views>>> && ...);
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)  
requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
};

1 iterator::iterator_concept is defined as follows:
(1.1) — If all-random-access<Const, Views...> is modeled, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if all-bidirectional<Const, Views...> is modeled, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, if all-forward<Const, Views...> is modeled, then iterator_concept denotes forward_iterator_tag.
(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 iterator::iterator_category is present if and only if all-forward<Const, Views...> is modeled.
3 If the invocation of any non-const member function of iterator exits via an exception, the iterator acquires a singular value.

constexpr explicit iterator(tuple<iterator_t<maybe-const<Const, Views>>>... current);

4 Effects: Initializes current_ with std::move(current).

constexpr iterator(iterator<Const> i)  
requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);

5 Effects: Initializes current_ with std::move(i.current_).

constexpr auto operator*() const;

6 Effects: Equivalent to:
return tuple_transform([](auto& i) -> decltype(auto) { return *i; }, current_);

constexpr iterator& operator++();

7 Effects: Equivalent to:
tuple_for_each([](auto& i) { ++i; }, current_);
return *this;

§ 26.7.24.3
constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator operator++(int) requires all-forward<Const, Views...>;

Effects: Equivalent to:
auto tmp = *this;
+++this;
return tmp;

constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;

Effects: Equivalent to:
tuple-for-each([](auto i) { --i; }, current_);
return *this;

constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type x)
requires all-random-access<Const, Views...>;

Effects: Equivalent to:
tuple-for-each([]<class I>(I& i) { i += iter_difference_t<I>(x); }, current_);
return *this;

constexpr iterator operator-=(difference_type x)
requires all-random-access<Const, Views...>;

Effects: Equivalent to:
tuple-for-each([]<class I>(I& i) { i -= iter_difference_t<I>(x); }, current_);
return *this;

custom auto operator[](difference_type n) const
requires all-random-access<Const, Views...>;

Effects: Equivalent to:
return tuple-transform([]<class I>(I& i) -> decltype(auto) {
    return i[iter_difference_t<I>(n)];
}, current_);

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);

Returns:

— x.current_ == y.current_ if all-bidirectional<Const, Views...> is true.

— Otherwise, true if there exists an integer 0 ≤ i < sizeof...(Views) such that bool(std::get<i>(x.current_)) is true.

[Note 1: This allows zip_view to model common_range when all constituent views model common_range.
—end note]

— Otherwise, false.

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
requires all-random-access<Const, Views...>;

Returns: x.current_ <=> y.current_.

friend constexpr iterator operator*(const iterator& i, difference_type n)
requires all-random-access<Const, Views...>;

§ 26.7.24.3 1252
friend constexpr iterator operator+(difference_type n, const iterator& i)  
requires all_random_access<Const, Views...>;  

Effects: Equivalent to:

auto r = i;  
r += n;  
return r;

friend constexpr iterator operator-(const iterator& i, difference_type n)  
requires all_random_access<Const, Views...>;  

Effects: Equivalent to:

auto r = i;  
r -= n;  
return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)  
requires (sized_sentinel_for<iterator_t<maybe_const<Const, Views>>,  
iterator_t<maybe_const<Const, Views>>> && ...);  

Let DIST(i) be difference_type(std::get<i>(x.current_)) - std::get<i>(y.current_)).  

Returns: The value with the smallest absolute value among DIST(n) for all integers 0 ≤ n < sizeof...(Views).

friend constexpr auto iter_move(const iterator& i) noexcept(see below);

Effects: Equivalent to:

return tuple_transform(ranges::iter_move, i.current_);  

Remarks: The exception specification is equivalent to:

(noexcept(ranges::iter_move(declval<iterator_t<maybe_const<Const, Views>>,  
Views>>>())) && ...) &&  
(is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe_const<Const, Views>>> && ...)  

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)  
requires (indirectly_swappable<iterator_t<maybe_const<Const, Views>>,  
Views>>> && ...);  

Effects: For every integer 0 ≤ i < sizeof...(Views), performs:

ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_)))

for every integer 0 ≤ i < sizeof...(Views).

26.7.24.4 Class template zip_view::sentinel

namespace std::ranges {

template<input_range... Views>  
requires (view<Views> && ...) && (sizeof...(Views) > 0)  
template<bool Const>  
class zip_view<Views...>::sentinel {

tuple<sentinel_t<maybe_const<Const, Views>>, ...> end;  
// exposition only

constexpr explicit sentinel(tuple<sentinel_t<maybe_const<Const, Views>>, ...> end);  
// exposition only

class zip_view<Views...>::sentinel {

public:

sentinel() = default;  
constexpr sentinel(sentinel<!Const> i)  
requires Const && (convertible_to<sentinel_t<Views>, sentinel_t<const Views>> && ...);

template<bool OtherConst>  
requires (sentinel_for<sentinel_t<maybe_const<Const, Views>>,  
iterator_t<maybe_const<OtherConst, Views>>> && ...)

friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
template<
    bool OtherConst>
friend constexpr common_type_t<
    range_difference_t<
    maybe-const<
    OtherConst, Views>>...>
operator-(
    const iterator<
    OtherConst>& x, const sentinel& y);

};

conestexpr explicit sentinel( tuple<
    sentinel_t<
        maybe-const<Const, Views>>...> end);

Effects: Initializes end_ with end.

constexpr sentinel(sentinel<!Const> i)
requires Const && (convertible_to<
    sentinel_t<Views>, sentinel_t<const Views>> && ...);

Effects: Initializes end_ with std::move(i.end_).

template<
    bool OtherConst>
friend constexpr common_type_t<
    range_difference_t<
    maybe-const<
    OtherConst, Views>>...>
operator-(
    const iterator<
    OtherConst>& x, const sentinel& y);

Returns: The value with the smallest absolute value among DIST(n) for all integers 0 ≤ n < sizeof...(Views).

Effects: Equivalent to: return -(x - y);

§ 26.7.25  Zip transform view

26.7.25.1  Overview

zip_transform_view takes an invocable object and any number of views and produces a view whose M\textsuperscript{th} element is the result of applying the invocable object to the M\textsuperscript{th} elements of all views.

The name views::zip_transform denotes a customization point object (16.3.3.3.5). Let F be a subexpression, and let Es... be a pack of subexpressions.

(2.1) If Es is an empty pack, let FD be decay_t<decltype(F)>.

(2.1.1) If move_constructible<FD> && regular_invocable<FD&> is false, or if decay_t<invoke_result_t<FD&>> is not an object type, views::zip_transform(F, Es...) is ill-formed.

(2.1.2) Otherwise, the expression views::zip_transform(F, Es...) is expression-equivalent to ((void)F, auto(views::empty<decay_t<invoke_result_t<FD&>>>))

(2.2) Otherwise, the expression views::zip_transform(F, Es...) is expression-equivalent to zip_transform_view(F, Es...).
Example 1:

```cpp
vector v1 = {1, 2};
vector v2 = {4, 5, 6};

for (auto i : views::zip_transform(plus(), v1, v2)) {
    // prints 5 7
    cout << i << ' ';
}
```

—end example

### 26.7.25.2 Class template zip_transform_view

```cpp
namespace std::ranges {

    template<move_constructible F, input_range... Views>
    requires (view<Views> && ... && is_object_v<F> &&
        regular_invocable<F, range_reference_t<Views>...> &&
        can_reference<invoke_result_t<F, range_reference_t<Views>...>>) class zip_transform_view : public view_interface<zip_transform_view<F, Views...>> {
        movable-box<F> fun_;  // exposition only
        zip_view<Views...> zip_;  // exposition only

        using InnerView = zip_view<Views...>;  // exposition only
        template<bool Const> using ziperator = iterator_t<maybe-const<Const, InnerView>>;  // exposition only
        template<bool Const> using zentinel = sentinel_t<maybe-const<Const, InnerView>>;  // exposition only

        // 26.7.25.3, class template zip_transform_view::iterator
        template<bool> class iterator;
        // exposition only

        // 26.7.25.4, class template zip_transform_view::sentinel
        template<bool> class sentinel;  // exposition only

    public:
        zip_transform_view() = default;

        constexpr explicit zip_transform_view(F fun, Views... views);

        constexpr auto begin() { return iterator<false>(*this, zip_.begin()); }

        constexpr auto begin() const requires range<const InnerView> &&
            regular_invocable<Const, range_reference_t<const Views>...> { return iterator<true>(*this, zip_.begin()); }

        constexpr auto end() {
            if constexpr (common_range<InnerView>) {
                return iterator<false>(*this, zip_.end());
            } else {
                return sentinel<false>(stp_.end());
            }
        }

        constexpr auto end() const requires range<const InnerView> &&
            regular_invocable<Const, range_reference_t<const Views>...> { if constexpr (common_range<const InnerView>) {
                return iterator<true>(*this, zip_.end());
            } else {
                return sentinel<true>(stp_.end());
            }
        }
    }
}
```
constexpr auto size() requires sized_range<InnerView> {
    return zip_.size();
}

constexpr auto size() const requires sized_range<const InnerView> {
    return zip_.size();
};

template<class F, class... Rs>
zip_transform_view(F, Rs&&...) -> zip_transform_view<F, views::all_t<Rs>...>;

constexpr explicit zip_transform_view(F fun, Views... views);  

Effects: Initializes fun_ with std::move(fun) and zip_ with std::move(views)....

26.7.25.3 Class template zip_transform_view::iterator  

namespace std::ranges {
    template<move_constructible F, input_range... Views>
    requires (view<View> && ...) && (sizeof...(Views) > 0) && is_object_v<F> &&
              regular_invocable<F&, range_reference_t<Views>...> &&
              can-reference<invoke_result_t<F&, range_reference_t<Views>...>>
    template<bool Const>
    class zip_transform_view<F, Views...>::iterator {
        using Parent = maybe-const<Const, zip_transform_view>;  // exposition only
        using Base = maybe-const<Const, InnerView>;  // exposition only
        Parent* parent_ = nullptr;  // exposition only
        ziperator<Const> inner_;  // exposition only

        constexpr iterator(Parent& parent, ziperator<Const> inner);  // exposition only

        public:
            using iterator_category = see below;  // not always present
            using iterator_concept = typename ziperator<Const>::iterator_concept;
            using value_type = remove_cvref_t<invoke_result_t<maybe-const<Const, F> &,
                                               range_reference_t<maybe-const<Const, Views>...>>;
            using difference_type = range_difference_t<Base>;

            iterator() = default;
            constexpr iterator(iterator<false> i) requires Const && convertible_to<ziperator<Const>>;

            decltype(auto) operator*() const noexcept(see below);
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;
            constexpr iterator& operator-=(difference_type x) requires random_access_range<Base>;
            constexpr iterator& operator[](difference_type n) const requires random_access_range<Base>;

            friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<ziperator<Const>>;
            friend constexpr auto operator<(const iterator& x, const iterator& y) requires random_access_range<Base>;
    }
}
friend constexpr iterator operator+(const iterator& i, difference_type n) requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i) requires random_access_range<Base>;
friend constexpr iterator operator-(const iterator& i, difference_type n) requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<zisitor<Const>, zisitor<Const>>;
};

1 The member typedef-name iterator::iterator_category is defined if and only if Base models forward_range. In that case, iterator::iterator_category is defined as follows:

(1.1) If invoke_result_t<maybe-const<Const, F>&, range_reference_t<maybe-const<Const, Views>>...> is not a reference, iterator_category denotes input_iterator_tag.

(1.2) Otherwise, let Cs denote the pack of types iterator_traits<iterator_t<maybe-const<Const, Views>>>::iterator_category...

(1.2.1) If (derived_from<Cs, random_access_iterator_tag> && ...) is true, iterator_category denotes random_access_iterator_tag.

(1.2.2) Otherwise, if (derived_from<Cs, bidirectional_iterator_tag> && ...) is true, iterator_category denotes bidirectional_iterator_tag.

(1.2.3) Otherwise, if (derived_from<Cs, forward_iterator_tag> && ...) is true, iterator_category denotes forward_iterator_tag.

(1.2.4) Otherwise, iterator_category denotes input_iterator_tag.

constexpr iterator(Parent& parent, zisitor<Const> inner);

Effects: Initializes parent_ with addressof(parent) and inner_ with std::move(inner).

constexpr iterator(iterator<Const> i) requires Const && convertible_to<zisitor<false>, zisitor<Const>>;

Effects: Initializes parent_ with i.parent_ and inner_ with std::move(i.inner_).

constexpr decltype(auto) operator*() const noexcept(see below);

Effects: Equivalent to:

return apply([&](const auto&... iters) -> decltype(auto) {
    return invoke(*parent_->fun_, *iters...);
}, inner_.current_);

Remarks: Let Is be the pack 0, 1, ..., (sizeof...(Views)-1). The exception specification is equivalent to: noexcept(invoke(*parent_->fun_, std::get<Is>(inner_.current_))...)).

constexpr iterator& operator++();

Effects: Equivalent to:

++inner_;
return *this;

constexpr void operator++(int);

Effects: Equivalent to: +++this.

constexpr iterator operator++(int) requires forward_range<Base>;

Effects: Equivalent to:

auto tmp = *this;
+++this;
return tmp;
constexpr iterator operator--() requires bidirectional_range<Base>;

Effects: Equivalent to:

--inner_;
return *this;

constexpr iterator operator--(int) requires bidirectional_range<Base>;

Effects: Equivalent to:

auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;

Effects: Equivalent to:

inner_ += x;
return *this;

constexpr iterator& operator-=(difference_type x) requires random_access_range<Base>;

Effects: Equivalent to:

inner_ -= x;
return *this;

constexpr decltype(auto) operator[](difference_type n) const requires random_access_range<Base>;

Effects: Equivalent to:

return apply(#class... Is>(const Is&... iters) -> decltype(auto) { return invoke(*parent_->fun_, iters[iter_difference_t<Is>(n)]...); }, inner_.current_);

friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<ziperator<Const>>;
friend constexpr auto operator<=>(const iterator& x, const iterator& y) requires random_access_range<Base>;

Let op be the operator.

Effects: Equivalent to: return x.inner_ op y.inner_;

friend constexpr iterator operator+(const iterator& i, difference_type n) requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i) requires random_access_range<Base>;

Effects: Equivalent to: return iterator(*i.parent_, i.inner_ + n);

friend constexpr iterator operator-(const iterator& i, difference_type n) requires random_access_range<Base>;

Effects: Equivalent to: return iterator(*i.parent_, i.inner_ - n);

friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<ziperator<Const>>, ziperator<Const>;

Effects: Equivalent to: return x.inner_ - y.inner_;

26.7.25.4 Class template zip_transform_view::sentinel

namespace std::ranges {

template<move_constructible F, input_range... Views>
requires (view<Views> && ... ) && (sizeof...(Views) > 0) && is_object_v<F> &&
regular_invocable<F&, range_reference_t<Views>...>
&& can_reference<invoke_result_t<F&, range_reference_t<Views>...>>
template<bool Const>
class zip_transform_view<F, Views...>::sentinel {

§ 26.7.25.4
```cpp
constexpr explicit sentinel(zentinel<Const> inner); // exposition only

public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> i)
        requires Const && convertible_to<sentinel<false>, sentinel<Const>>;

    template<bool OtherConst>
        requires sentinel_for<sentinel<Const>, ziperator<OtherConst>>
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

    template<bool OtherConst>
        requires sized_sentinel_for<sentinel<Const>, ziperator<OtherConst>>

friend constexpr range_difference_t<maybe-const<OtherConst, InnerView>>
    operator-(const sentinel& x, const iterator<OtherConst>& y);

4 Effects: Equivalent to: return x.inner_ - y.inner_;```

### 26.7.26 Adjacent view

#### 26.7.26.1 Overview

adjacent_view takes a view and produces a view whose \(M^\text{th}\) element is a tuple of references to the \(M^\text{th}\) through \((M + N - 1)^\text{th}\) elements of the original view. If the original view has fewer than \(N\) elements, the resulting view is empty.

The name `views::adjacent<N>` denotes a range adaptor object (26.7.2). Given a subexpression \(E\) and a constant expression \(N\), the expression `views::adjacent<N>(E)` is expression-equivalent to

\[
((\text{void})E, \text{auto}(\text{views::empty<tuple<>}))\]

if \(N\) is equal to 0,

\[
\text{otherwise, adjacent_view<views::all_t<decltype((E))>, N>(E)}.
\]

**Example 1:**

```cpp
type v = {1, 2, 3, 4};
```
for (auto i : v | views::adjacent<2>) {
    cout << "(" << std::get<0>(i) << " , " << std::get<1>(i) << " ) ; // prints (1, 2) (2, 3) (3, 4) \\
}
—end example

3 Define \texttt{REPEAT}(T, N) as a pack of \( N \) types, each of which denotes the same type as \( T \).

26.7.26.2 Class template \texttt{adjacent\_view}  

namespace std::ranges {
    template<forward_range V, size_t N>
    requires view<V> && (N > 0)
    class adjacent_view : public view_interface<adjacent_view<V, N>> {
        V base_ = V();  // exposition only

        // 26.7.26.3, class template adjacent_view::\texttt{iterator}
        template<bool> class iterator;  // exposition only

        // 26.7.26.4, class template adjacent_view::\texttt{sentinel}
        template<bool> class sentinel;  // exposition only

        struct as_sentinel{};  // exposition only

        public:
            adjacent_view() requires default_initializable<V> = default;
            constexpr explicit adjacent_view(V base);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr auto begin() requires (!simple_view<V>) {
                return iterator<false>(ranges::begin(base_), ranges::end(base_));
            }

            constexpr auto begin() const requires range<const V> {
                return iterator<true>(ranges::begin(base_), ranges::end(base_));
            }

            constexpr auto end() requires (!simple_view<V>) {

        friend constexpr iterator operator+(const iterator& x, difference_type n)
            requires random_access_range<Base>;
        friend constexpr iterator operator+(difference_type n, const iterator& x)
            requires random_access_range<Base>;
        friend constexpr iterator operator-(const iterator& x, difference_type n)
            requires random_access_range<Base>;
    }
}
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

friend constexpr auto iter_move(const iterator& i) noexcept(see below);
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
    requires indirectly_swappable<iterator_t<Base>>;
};

1 iterator::iterator_concept is defined as follows:
   (1.1) — If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
   (1.2) — Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
   (1.3) — Otherwise, iterator_concept denotes forward_iterator_tag.
2 If the invocation of any non-const member function of iterator exits via an exception, the iterator acquires a singular value.
constexpr iterator(iterator_t<Base> first, sentinel_t<Base> last);
   Postconditions: current_[0] == first is true, and for every integer 1 ≤ i < N, current_[i] == ranges::next(current_[i-1], 1, last) is true.
constexpr iterator(as_sentinel, iterator_t<Base> first, iterator_t<Base> last);
   Postconditions: If Base does not model bidirectional_range, each element of current_ is equal to last. Otherwise, current_[N-1] == last is true, and for every integer 0 ≤ i < (N - 1), current_[i] == ranges::prev(current_[i+1], 1, first) is true.
constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
   Effects: Initializes each element of current_ with the corresponding element of i. current_ as an xvalue.
constexpr auto operator*() const;
   Effects: Equivalent to:
           return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);
constexpr iterator& operator++();
   Preconditions: current_.back() is incrementable.
   Postconditions: Each element of current_ is equal to ranges::next(i), where i is the value of that element before the call.
   Returns: *this.
constexpr iterator& operator++(int);
   Effects: Equivalent to:
           auto tmp = *this;
           +++this;
           return tmp;
constexpr iterator& operator--() requires bidirectional_range<Base>;
   Preconditions: current_.front() is decrementable.
   Postconditions: Each element of current_ is equal to ranges::prev(i), where i is the value of that element before the call.
   Returns: *this.
constexpr iterator& operator--(int) requires bidirectional_range<Base>;
   Effects: Equivalent to:
§ 26.7.26.3
auto tmp = *this;
---*this;
return tmp;

constexpr iterator& operator+=(difference_type x)
requires random_access_range<Base>;

Preconditions: current_.back() + x has well-defined behavior.
Postconditions: Each element of current_ is equal to i + x, where i is the value of that element before the call.
Returns: *this.

constexpr iterator& operator-=(difference_type x)
requires random_access_range<Base>;

Preconditions: current_.front() - x has well-defined behavior.
Postconditions: Each element of current_ is equal to i - x, where i is the value of that element before the call.
Returns: *this.

constexpr auto operator[](difference_type n) const
requires random_access_range<Base>;

Effects: Equivalent to:
return tuple-transform(\[&\](auto& i) -> decltype(auto) { return i[n]; }, current_);

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: x.current_.back() == y.current_.back().

friend constexpr bool operator<(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return y < x;

friend constexpr bool operator>(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return !y < x;

friend constexpr bool operator<=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return !x < y;

friend constexpr bool operator>=(const iterator& x, const iterator& y)
requires random_access_range<Base> &
three_way_comparable<iterator_t<Base>>;

Returns: x.current_.back() >= y.current_.back().

friend constexpr iterator operator+(const iterator& i, difference_type n)
requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
r += n;
return r;
friend constexpr iterator operator-(const iterator& i, difference_type n)
   requires random_access_range<Base>;

   Effects: Equivalent to:
            auto r = i;
            r -= n;
            return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)
   requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

   Effects: Equivalent to: return x.current_.back() - y.current_.back();

friend constexpr auto iter_move(const iterator& i) noexcept(see below);

   Effects: Equivalent to: return tuple-transform(ranges::iter_move, i.current_);

   Remarks: The exception specification is equivalent to:
            noexcept(ranges::iter_move(declval<const iterator_t<Base>&>())) &&
            is_nothrow_move_constructible_v<range_rvalue_reference_t<Base>>

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
   requires indirectly_swappable<iterator_t<Base>>;

   Preconditions: None of the iterators in l.current_ is equal to an iterator in r.current_.

   Effects: For every integer 0 ≤ i < N, performs ranges::iter_swap(l.current_[i], r.current_[i]).

   Remarks: The exception specification is equivalent to:
            noexcept(ranges::iter_swap(declval<iterator_t<Base>>(), declval<iterator_t<Base>>()))

26.7.26.4 Class template adjacent_view::sentinel

namespace std::ranges {
    template<forward_range V, size_t N>
        requires view<V> && (N > 0)
    template<bool Const>
        class adjacent_view<V, N>::sentinel {
        using Base = maybe-const<Const, V>;
        sentinel_t<Base> end_ = sentinel_t<Base>();
        constexpr explicit sentinel(sentinel_t<Base> end); // exposition only
        public:
            sentinel() = default;
            constexpr sentinel(sentinel<!Const> i)
                requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>; // exposition only
        template<bool OtherConst>
            requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
        friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y); // exposition only
        template<bool OtherConst>

        friend constexpr range_difference_t<maybe-const<OtherConst, V>>
            operator-(const iterator<OtherConst>& x, const sentinel& y); // exposition only
        template<bool OtherConst>
            requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
        friend constexpr range_difference_t<maybe-const<OtherConst, V>>
            operator-(const sentinel& y, const iterator<OtherConst>& x);
    }

    constexpr explicit sentinel(sentinel_t<Base> end);

   Effects: Initializes end_ with end.
constexpr sentinel(sentinel<!Const> i)
  requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

 Effects: Initializes end_ with std::move(i.end_).

template<bool OtherConst>
  requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>> friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

 Effects: Equivalent to: return x.current_.back() == y.end_;

template<bool OtherConst>
  requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>> friend constexpr range_difference_t<maybe-const<OtherConst, V>> operator-(const iterator<OtherConst>& x, const sentinel& y);

 Effects: Equivalent to: return y.end_ - x.current_.back();

26.7.27 Adjacent transform view

26.7.27.1 Overview

adjacent_transform_view takes an invocable object and a view and produces a view whose $M$th element is the result of applying the invocable object to the $M$th through $(M + N − 1)$th elements of the original view. If the original view has fewer than $N$ elements, the resulting view is empty.

The name views::adjacent_transform<N> denotes a range adaptor object (26.7.2). Given subexpressions $E$ and $F$ and a constant expression $N$:

(2.1) — If $N$ is equal to 0, views::adjacent_transform<N>(E, F) is expression-equivalent to ((void)E, views::zip_transform(F)), except that the evaluations of $E$ and $F$ are indeterminately sequenced.

(2.2) — Otherwise, the expression views::adjacent_transform<N>(E, F) is expression-equivalent to adjacent_transform_view<views::all_t<decltype((E))>, decay_t<decltype((F))>, N>(E, F).

[Example 1:]

```cpp
template<forward_range V, move_constructible F, size_t N>
  requires view<V> && (N > 0) && is_object_v<F> &&
  regular_invocable<F&>, REPEAT(range_reference_t<V>, N)... &&
  can-reference<invoke_result_t<F&>, REPEAT(range_reference_t<V>, N)...>>
class adjacent_transform_view : public view_interface<adjacent_transform_view<V, F, N>> {
    using InnerView = adjacent_view<V, N>; // exposition only
    using adjacent_view<V, N> inner_; // exposition only
    template<bool Const>
      using inner_iterator = iterator_t<maybe-const<Const, InnerView>>; // exposition only
    template<bool Const>
      using inner_sentinel = sentinel_t<maybe-const<Const, InnerView>>; // exposition only
  }
```

26.7.27.2 Class template adjacent_transform_view

```cpp
namespace std::ranges {

```
// 26.7.27.4, class template adjacent_transform_view::sentinel
template<bool> class sentinel; // exposition only

public:
adjacent_transform_view() = default;
constexpr explicit adjacent_transform_view(V base, F fun);

constexpr V base() const & requires copy_constructible<V> { return inner_.base(); }
constexpr V base() && { return std::move(inner_.base()); }

constexpr auto begin() {
    return iterator<false>(*this, inner_.begin());
}

constexpr auto begin() const requires range<const InnerView> && regular_invocable<const F&, REPEAT(range_reference_t<const V>, N)...> { return iterator<true>(*this, inner_.begin()); }

constexpr auto end() { if constexpr (common_range<InnerView>) { return iterator<false>(*this, inner_.end()); } else { return sentinel<false>(inner_.end()); } }

constexpr auto end() const requires range<const InnerView> && regular_invocable<const F&, REPEAT(range_reference_t<const V>, N)...> { if constexpr (common_range<const InnerView>) { return iterator<true>(*this, inner_.end()); } else { return sentinel<true>(inner_.end()); } }

constexpr auto size() requires sized_range<InnerView> { return inner_.size(); }
constexpr auto size() const requires sized_range<const InnerView> { return inner_.size(); }

constexpr explicit adjacent_transform_view(V base, F fun);

Effects: Initializes fun_ with std::move(fun) and inner_ with std::move(base).

26.7.27.3 Class template adjacent_transform_view::iterator
[range.adjoint.transform.iterator]
namespace std::ranges {
    template<forward_range V, move_constructible F, size_t N>
    requires view<V> && (N > 0) && is_object_v<F> &&
    regular_invocable<F, REPEAT(range_reference_t<const V>, N)...> &&
    can_reference<invoke_result_t<F&>, REPEAT(range_reference_t<const V>, N)...>>
    template<bool Const>
    class adjacent_transform_view<V, F, N>::iterator {
        using Parent = maybe-const<Const, adjacent_transform_view>;
        using Base = maybe-const<Const, V>;
        Parent* parent_ = nullptr;
    };
}
inner-iterator<Const> inner_;  // exposition only
constexpr iterator(Parent& parent, inner-iterator<Const> inner);  // exposition only

public:
using iterator_category = see below;
using iterator_concept = typename inner-iterator<Const>::iterator_concept;
using value_type = remove_cvref_t<invoke_result_t<maybe-const<Const, F>&, REPEAT(range_reference_t<Base>, N)...>>;
using difference_type = range_difference_t<Base>;
iterator() = default;
constexpr iterator(iterator<!Const> i) requires Const && convertible_to<inner-iterator<false>, inner-iterator<Base>>;

constexpr decltype(auto) operator*() const noexcept(see below);
constexpr iterator operator++();
constexpr iterator operator--() requires bidirectional_range<Base>;
constexpr iterator operator--(int) requires bidirectional_range<Base>;
constexpr iterator operator+=(difference_type x) requires random_access_range<Base>;
constexpr iterator operator-=(difference_type x) requires random_access_range<Base>;

friend constexpr bool operator==(const iterator& x, const iterator& y);  
friend constexpr bool operator<(const iterator& x, const iterator& y) requires random_access_range<Base>;
friend constexpr bool operator>(const iterator& x, const iterator& y) requires random_access_range<Base>;
friend constexpr bool operator<=(const iterator& x, const iterator& y) requires random_access_range<Base>;
friend constexpr bool operator>=(const iterator& x, const iterator& y) requires random_access_range<Base>;

friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<inner-iterator<Const>, inner-iterator<Const>>;

};

1 The member typedef-name iterator::iterator_category is defined as follows:

(1.1) If invoke_result_t<maybe-const<Const, F>&, REPEAT(range_reference_t<Base>, N)...> is not a reference, iterator_category denotes input_iterator_tag.

(1.2) Otherwise, let C denote the type iterator_traits<iterator_t<Base>>::iterator_category.

(1.2.1) If derived_from<C, random_access_iterator_tag> is true, iterator_category denotes random_access_iterator_tag.

(1.2.2) Otherwise, if derived_from<C, bidirectional_iterator_tag> is true, iterator_category denotes bidirectional_iterator_tag.

(1.2.3) Otherwise, if derived_from<C, forward_iterator_tag> is true, iterator_category denotes forward_iterator_tag.

(1.2.4) Otherwise, iterator_category denotes input_iterator_tag.
constexpr iterator(const Parent& parent, inner_iterator<Const> inner);

**Effects:** Initializes `parent_` with `&parent` and `inner_` with `std::move(inner)`.

constexpr iterator(iterator<!Const> i)
    requires Const && convertible_to<inner_iterator<false>, inner_iterator<Const>>;

**Effects:** Initializes `parent_` with `i.parent_` and `inner_` with `std::move(i.inner_)`.

constexpr decltype(auto) operator*() const noexcept;

**Effects:** Equivalent to:

```
return apply([&](const auto&... iters) -> decltype(auto) {
    return invoke(*parent_->fun_, *iters...);
}, inner_.current_);
```

**Remarks:** Let `Is` be the pack `0, 1, ..., (N-1)`. The exception specification is equivalent to:

`noexcept(invoke(*parent_->fun_, std::get<Is>(inner_.current_)...))`

constexpr iterator& operator++();

**Effects:** Equivalent to:

```
++inner_;  
return *this;
```

constexpr iterator operator++(int);

**Effects:** Equivalent to:

```
auto tmp = *this;  
++*this;  
return tmp;
```

constexpr iterator& operator--() requires bidirectional_range<Base>;

**Effects:** Equivalent to:

```
--inner_;  
return *this;
```

constexpr iterator operator--(int) requires bidirectional_range<Base>;

**Effects:** Equivalent to:

```
auto tmp = *this;  
--*this;  
return tmp;
```

constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
inner_ += x;

};

1 iterator::iterator_concept is defined as follows:

(1.1) If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.

§ 26.7.28.7
— Otherwise, if $Base$ models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.

(1.3) — Otherwise, iterator_concept denotes forward_iterator_tag.

```cpp
constexpr iterator (Parent* parent, iterator_t<Base> current, range_difference_t<Base> missing = 0);
```

2 Effects: Initializes current_ with current, end_ with ranges::end(parent->base_), n_ with parent->n_, and missing_ with missing.

```cpp
constexpr iterator (iterator<!Const> i)
requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>
&& convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

3 Effects: Initializes current_ with std::move(i.current_), end_ with std::move(i.end_), n_ with i.n_, and missing_ with i.missing_.

```cpp
constexpr iterator_t<Base> base() const;
```

4 Returns: current_.

```cpp
constexpr value_type operator*() const;
```

5 Preconditions: current_ != end_ is true.

6 Returns: views::take(subrange(current_, end_), n_).

```cpp
constexpr operator++();
```

7 Preconditions: current_ != end_ is true.

8 Effects: Equivalent to:

```cpp
missing_ = ranges::advance(current_, n_, end_);
return *this;
```

```cpp
constexpr iterator operator++(int);  
```

9 Effects: Equivalent to:

```cpp
auto tmp = *this;  
+++this;
return tmp;
```

```cpp
constexpr iterator& operator--() requires bidirectional_range<Base>;
```

10 Effects: Equivalent to:

```cpp
ranges::advance(current_, missing_ - n_);  
missing_ = 0;  
return *this;
```

```cpp
constexpr iterator& operator--(int) requires bidirectional_range<Base>;
```

11 Effects: Equivalent to:

```cpp
auto tmp = *this;  
--*this;
return tmp;
```

```cpp
constexpr iterator& operator+=(difference_type x)  
requires random_access_range<Base>;
```

12 Preconditions: If $x$ is positive, ranges::distance(current_, end_) > n_ * (x - 1) is true.

[Note 1: If $x$ is negative, the Effects paragraph implies a precondition. — end note]

13 Effects: Equivalent to:

```cpp
if (x > 0) {
    ranges::advance(current_, n_ * (x - 1));  
    missing_ = ranges::advance(current_, n_, end_);  
} else if (x < 0) {
    ranges::advance(current_, n_ * x + missing_);
missing_ = 0;
}
return *this;

constexpr iterator& operator-=(difference_type x)
requires random_access_range<Base>;

Effects: Equivalent to: return *this += -x;

constexpr value_type operator[](difference_type n) const
requires random_access_range<Base>;

Returns: *(this + n).

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: x.current_ == y.current_.

friend constexpr bool operator==(const iterator& x, default_sentinel_t);

Returns: x.current_ == x.end_.

friend constexpr bool operator<(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return y < x;

requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
 r -= n;
return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)
requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

Returns: (x.current_ - y.current_ + x.missing_ - y.missing_) / x.n.
friend constexpr difference_type operator-(default_sentinel_t y, const iterator& x)  
requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;  

Returns: \(\text{div-ceil}(x.\text{end_} - x.\text{current_}, x.\text{n_})\).

friend constexpr difference_type operator-(const iterator& x, default_sentinel_t y)  
requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;  

Effects: Equivalent to: return -(y - x);

26.7.29 Slide view

26.7.29.1 Overview

slide_view takes a view and a number \(N\) and produces a view whose \(M^{th}\) element is a view over the \(M^{th}\) through \((M + N - 1)^{th}\) elements of the original view. If the original view has fewer than \(N\) elements, the resulting view is empty.

The name \texttt{views::slide} denotes a range adaptor object (26.7.2). Given subexpressions \(E\) and \(N\), the expression views::slide\((E, N\)) is expression-equivalent to slide_view\((E, N)\).

[Example 1:

```cpp
vector v = {1, 2, 3, 4};
for (auto i : v | views::slide(2)) {
    cout << '[' << i[0] << ', ' << i[1] << ']' << endl; // prints [1, 2] [2, 3] [3, 4]
}
```
—end example]

        constexpr auto begin() const requires slide-caches-nothing<const V>;
        constexpr auto end()  
            requires (!simple-view<V> && slide-caches-nothing<const V>));
constexpr auto end() const requires slide-caches-nothing<const V>;
constexpr auto size() requires sized_range<V>;
constexpr auto size() const requires sized_range<const V>;

};

template<class R>
slide_view(R&&, range_difference_t<R>) -> slide_view<views::all_t<R>>;

#endif

constexpr explicit slide_view(V base, range_difference_t<V> n);
Preconditions: \( n > 0 \) is true.
Effects: Initializes base_ with std::move(base) and n_ with n.

constexpr auto begin() requires (!((simple-view<V> && slide-caches-nothing<const V>)));
Returns:
(3.1) — If V models slide-caches-first,
\[
\text{iterator}<\text{false}>(\text{ranges::begin(base_)}, \text{ranges::next(\text{ranges::begin(base_), } n_ - 1, \text{ranges::end(base_)}), } n_)
\]
(3.2) — Otherwise, \text{iterator}<\text{false}>(\text{ranges::begin(base_), } n_).
Remarks: In order to provide the amortized constant-time complexity required by the range concept, this function caches the result within the slide_view for use on subsequent calls when V models slide-caches-first.

constexpr auto begin() const requires slide-caches-nothing<const V>;
Returns: iterator<true>(ranges::begin(base_), n_).

constexpr auto end() requires (!((simple-view<V> && slide-caches-nothing<const V>)));
Returns:
(6.1) — If V models slide-caches-nothing,
\[
\text{iterator}<\text{false}>(\text{ranges::begin(base_) + range_difference_t<V>(size())}, n_)
\]
(6.2) — Otherwise, if V models slide-caches-last,
\[
\text{iterator}<\text{false}>(\text{ranges::prev(\text{ranges::end(base_), } n_ - 1, \text{ranges::begin(base_)})}, n_)
\]
(6.3) — Otherwise, if V models common_range,
\[
\text{iterator}<\text{false}>(\text{ranges::end(base_), } \text{ranges::end(base_)}, n_)
\]
(6.4) — Otherwise, sentinel(\text{ranges::end(base_)}).
Remarks: In order to provide the amortized constant-time complexity required by the range concept, this function caches the result within the slide_view for use on subsequent calls when V models slide-caches-last.

constexpr auto end() const requires slide-caches-nothing<const V>;
Returns: begin() + range_difference_t<const V>(size()).
constexpr auto size() requires sized_range<V>;
constexpr auto size() const requires sized_range<const V>;
Effects: Equivalent to:
\[
\text{auto sz = ranges::distance(base_) - n_ + 1; if } (sz < 0) \text{ sz = 0; return to-unsigned-like(sz)};
\]

26.7.29.3 Class template slide_view::iterator
namespace std::ranges {
    template<forward_range V>

§ 26.7.29.3
friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
};

1 iterator::iterator_concept is defined as follows:

(1.1) — If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, iterator_concept denotes forward_iterator_tag.

2 If the invocation of any non-const member function of iterator exits via an exception, the iterator acquires a singular value.

constexpr iterator(iterator_t<Base> current, range_difference_t<Base> n) requires (!slide-caches-first<Base>);

Effects: Initializes current_ with current and n_ with n.

constexpr iterator(iterator_t<Base> current, iterator_t<Base> last_ele, range_difference_t<Base> n) requires slide-caches-first<Base>;

Effects: Initializes current_ with current, last_ele_ with last_ele, and n_ with n.

constexpr iterator(iterator<!Const> i) requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

Effects: Initializes current_ with std::move(i.current_) and n_ with i.n_.

[Note 1: iterator<true> can only be formed when Base models slide-caches-nothing, in which case last_ele_ is not present. — end note]

constexpr auto operator*() const;

Returns: views::counted(current_, n_).

constexpr iterator& operator++();

Preconditions: current_ and last_ele_ (if present) are incremenntable.

Postconditions: current_ and last_ele_ (if present) are each equal to ranges::next(i), where i is the value of that data member before the call.

Returns: *this.

constexpr iterator operator++(int);

Effects: Equivalent to:

auto tmp = *this;
++*this;
return tmp;

constexpr iterator& operator--() requires bidirectional_range<Base>;

Preconditions: current_ and last_ele_ (if present) are decrementable.

Postconditions: current_ and last_ele_ (if present) are each equal to ranges::prev(i), where i is the value of that data member before the call.

Returns: *this.

constexpr iterator operator--(int) requires bidirectional_range<Base>;

Effects: Equivalent to:

auto tmp = *this;
--*this;
return tmp;
constexpr iterator operator+=(difference_type x)
requires random_access_range<Base>;

Preconditions: current_ + x and last_ele_ + x (if last_ele_ is present) have well-defined behavior.
Postconditions: current_ and last_ele_ (if present) are each equal to i + x, where i is the value of that data member before the call.

Returns: *this.

constexpr iterator operator-=(difference_type x)
requires random_access_range<Base>;

Preconditions: current_ - x and last_ele_ - x (if last_ele_ is present) have well-defined behavior.
Postconditions: current_ and last_ele_ (if present) are each equal to i - x, where i is the value of that data member before the call.

Returns: *this.

castexpr auto operator[](difference_type n) const
requires random_access_range<Base>;

Effects: Equivalent to: return views::counted(current_ + n, n_);

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: If last_ele_ is present, x.last_ele_ == y.last_ele_; otherwise, x.current_ == y.current_.

friend constexpr bool operator<(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Returns: x.current_ < y.current_.

friend constexpr bool operator<=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return !(y < x);

friend constexpr bool operator>(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return y < x;

friend constexpr bool operator>=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return !(x < y);

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
requires random_access_range<Base> &&
three_way_comparable<iterator_t.<Base>>;

Returns: x.current_ <=> y.current_.

friend constexpr iterator operator+(const iterator& i, difference_type n)
requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
r += n;
return r;

friend constexpr iterator operator-(const iterator& i, difference_type n)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
r -= n;
return r;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

>Returns: If last_ele_ is present, x.last_ele_ - y.last_ele_; otherwise, x.current_ - y.current_.

### 26.7.29.4 Class slide_view::sentinel

```cpp
namespace std::ranges {
    template<forward_range V>
    requires view<V>
    class slide_view<V>::sentinel {
        sentinel_t<V> end_ = sentinel_t<V>(); // exposition only
        constexpr explicit sentinel(sentinel_t<V> end); // exposition only

    public:
        sentinel() = default;

        friend constexpr bool operator==(const iterator<false>& x, const sentinel& y);

        friend constexpr range_difference_t<V> operator-(const iterator<false>& x, const sentinel& y)
            requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
        friend constexpr range_difference_t<V> operator-(const sentinel& y, const iterator<false>& x)
            requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
    }
}
```

1 [Note 1: sentinel is used only when slide-caches-first<V> is true. — end note]
2 constexpr explicit sentinel(sentinel_t<V> end);
3 Effects: Initializes end_ with end.
4 friend constexpr bool operator==(const iterator<false>& x, const sentinel& y);
5 Returns: x.last_ele_ == y.end_.
6 friend constexpr range_difference_t<V> operator-(const iterator<false>& x, const sentinel& y)
        requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
7 Returns: x.last_ele_ - y.end_.
8 friend constexpr range_difference_t<V> operator-(const sentinel& y, const iterator<false>& x)
        requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
9 Returns: y.end_ - x.last_ele_.

### 26.7.30 Chunk by view

#### 26.7.30.1 Overview

chunk_by_view takes a view and a predicate, and splits the view into subrange_s between each pair of adjacent elements for which the predicate returns false.

The name views::chunk_by denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::chunk_by(E, F) is expression-equivalent to chunk_by_view(E, F).

[Example 1:

```cpp
vector v = {1, 2, 2, 3, 0, 4, 5, 2};

for (auto r : v | views::chunk_by(ranges::less_equal{})) {
    cout << '[';
    auto sep = "";
    for (auto i : r) {
        cout << sep << i;
```
26.7.30.2 Class template chunk_by_view

namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
        requires view<V> && is_object_v<Pred>
    class chunk_by_view : public view_interface<chunk_by_view<V, Pred>> {
        V base_ = V(); // exposition only
        movable-box<Pred> pred_; // exposition only

        // 26.7.30.3, class chunk_by_view::iterator
        class iterator; // exposition only

        public:
        chunk_by_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit chunk_by_view(V base, Pred pred);

        constexpr const Pred& pred() const;
        constexpr iterator begin();
        constexpr auto end();
        constexpr iterator_t<V> find-next(iterator_t<V>);
        // exposition only
        constexpr iterator_t<V> find-prev(iterator_t<V>) // exposition only
                    requires bidirectional_range<V>;
    };

    template<class R, class Pred>
    chunk_by_view(R&&, Pred) -> chunk_by_view<views::all_t<R>, Pred>;
}

constexpr explicit chunk_by_view(V base, Pred pred);

1 Effects: Initializes base_ with std::move(base) and pred_ with std::move(pred).

constexpr const Pred& pred() const;

2 Effects: Equivalent to: return *pred_;

constexpr iterator begin();

3 Preconditions: pred_.has_value() is true.

4 Returns: iterator(*this, ranges::begin(base_), find-next(ranges::begin(base_))).

5 Remarks: In order to provide the amortized constant-time complexity required by the range concept, this function caches the result within the chunk_by_view for use on subsequent calls.

constexpr auto end();

6 Effects: Equivalent to:

    if constexpr (common_range<V>) {
        return iterator(*this, ranges::end(base_), ranges::end(base_));
    } else {
        return default_sentinel;
    }

§ 26.7.30.2 1285
constexpr iterator_t<V> find-next(iterator_t<V> current);

Preconditions: pred_.has_value() is true.

Returns:
  ranges::next(ranges::adjacent_find(current, ranges::end(base_), not_fn(ref(*pred_))),
  1, ranges::end(base_))

constexpr iterator_t<V> find-prev(iterator_t<V> current) requires bidirectional_range<V>;

Preconditions:
(9.1) current is not equal to ranges::begin(base_).
(9.2) pred_.has_value() is true.

Returns: An iterator i in the range [ranges::begin(base_), current) such that:
(10.1) ranges::adjacent_find(i, current, not_fn(*pred_)) is equal to current; and
(10.2) if i is not equal to ranges::begin(base_), then bool(invoke(*pred_, *ranges::prev(i),
*1)) is false.

26.7.30.3 Class chunk_by_view::iterator

namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class chunk_by_view<V, Pred>::iterator {
        chunk_by_view* parent_ = nullptr; // exposition only
        iterator_t<V> current_ = iterator_t<V>(); // exposition only
        iterator_t<V> next_ = iterator_t<V>(); // exposition only

        constexpr iterator(chunk_by_view& parent, iterator_t<V> current, iterator_t<V> next); // exposition only

    public:
        using value_type = subrange<iterator_t<V>>;
        using difference_type = range_difference_t<V>;
        using iterator_category = input_iterator_tag;
        using iterator_concept = see below;

        iterator() = default;

        constexpr value_type operator*() const;
        constexpr iterator& operator++();
        constexpr iterator operator++(int);

        constexpr iterator& operator--() requires bidirectional_range<V>;
        constexpr iterator operator--(int) requires bidirectional_range<V>;

        friend constexpr bool operator==(const iterator& x, const iterator& y);
        friend constexpr bool operator==(const iterator& x, default_sentinel_t);
    };
}

1 iterator::iterator_concept is defined as follows:
(1.1) If V models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(1.2) Otherwise, iterator_concept denotes forward_iterator_tag.

constexpr iterator(chunk_by_view& parent, iterator_t<V> current, iterator_t<V> next);

Effects: Initializes parent_ with addressof(parent), current_ with current, and next_ with next.

constexpr value_type operator*() const;

Preconditions: current_ is not equal to next_.

Returns: subrange(current_, next_).

§ 26.7.30.3
constexpr iterator operator++();

Preconditions: current_ is not equal to next_.

Effects: Equivalent to:

    current_ = next_;  
    next_ = parent_->find-next(current_);  
    return *this;

constexpr iterator operator++(int);

Effects: Equivalent to:

    auto tmp = *this;  
    +++this;  
    return tmp;

constexpr iterator& operator--() requires bidirectional_range<V>;

Effects: Equivalent to:

    next_ = current_;  
    current_ = parent_->find-prev(next_);  
    return *this;

constexpr iterator& operator--(int) requires bidirectional_range<V>;

Effects: Equivalent to:

    auto tmp = *this;  
    --*this;  
    return tmp;

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: x.current_ == y.current_.

friend constexpr bool operator==(const iterator& x, default_sentinel_t);

Returns: x.current_ == x.next_.

26.7.31 Stride view

26.7.31.1 Overview

Stride view presents a view of an underlying sequence, advancing over \( n \) elements at a time, as opposed to the usual single-step succession.

The name \texttt{views::stride} denotes a range adaptor object (26.7.2). Given subexpressions \( E \) and \( N \), the expression \texttt{views::stride}(\( E \), \( N \)) is expression-equivalent to \texttt{stride_view}(\( E \), \( N \)).

[Example 1:]

```cpp
auto input = views::iota(0, 12) | views::stride(3);  
ranges::copy(input, ostream_iterator<int>(cout, " ")));  // prints 0 3 6 9  
ranges::copy(input | views::reverse, ostream_iterator<int>(cout, " "));  // prints 9 6 3 0
```

end example

26.7.31.2 Class template stride_view

namespace std::ranges {
    template<input_range V>  
    requires view<V>  
    class stride_view : public view_interface<stride_view<V>> {
        V base_;  
        range_difference_t<V> stride_;  
        // exposition only
        // 26.7.31.3, class template stride_view::iterator
        template<bool> class iterator;  
        // exposition only

        public:
            constexpr explicit stride_view(V base, range_difference_t<V> stride);  
            constexpr V base() const & requires copy_constructible<V> { return base_; }  
            constexpr V base() && { return std::move(base_); }  

§ 26.7.31.2

constexpr range_difference_t<V> stride() const noexcept;

constexpr auto begin() requires (!simple_view<V>) {

friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
friend constexpr difference_type operator-(default_sentinel_t y, const iterator& x) requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;
friend constexpr difference_type operator-(const iterator& x, default_sentinel_t y) requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;
friend constexpr range_rvalue_reference_t<Base> iter_move(const iterator& i) noexcept(noexcept(ranges::iter_move(i.current_)));
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_))) requires indirectly_swappable<iterator_t<Base>>;

1 iterator::iterator_concept is defined as follows:

(1.1) — If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, if Base models forward_range, then iterator_concept denotes forward_iterator_tag.
(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member typedef-name iterator_category is defined if and only if Base models forward_range. In that case, iterator::iterator_category is defined as follows:

(2.1) — Let C denote the type iterator_traits<iterator_t<Base>>::iterator_category.
(2.2) — If C models derived_from<random_access_iterator_tag>, then iterator_category denotes random_access_iterator_tag.
(2.3) — Otherwise, iterator_category denotes C.

constexpr iterator(Parent* parent, iterator_t<Base> current, range_difference_t<Base> missing = 0);

Effects: Initializes current_ with std::move(current), end_ with ranges::end(parent->base_), stride_ with parent->stride_, and missing_ with missing.

constexpr iterator(iterator<!Const> i) requires Const && convertible_to<iterator_t<V>, iterator_t<Base>> && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

Effects: Initializes current_ with std::move(i.current_), end_ with std::move(i.end_), stride_- with i.stride_, and missing_ with i.missing_.

constexpr iterator_t<Base> base() &&;

Returns: std::move(current_).

constexpr const iterator_t<Base>& base() const & noexcept;

Returns: current_.

constexpr iterator& operator++();

Preconditions: current_ != end_ is true.

Effects: Equivalent to:

missing_ = ranges::advance(current_, stride_, end_);
return *this;

constexpr void operator++(int);

Effects: Equivalent to: +++this;
constexpr iterator operator++(int) requires forward_range<Base>;

Effects: Equivalent to:
auto tmp = *this;
++*this;
return tmp;

constexpr iterator& operator--() requires bidirectional_range<Base>;

Effects: Equivalent to:
ranges::advance(current_, missing_ - stride_);
missing_ = 0;
return *this;

constexpr iterator& operator--(int) requires bidirectional_range<Base>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type n) requires random_access_range<Base>;

Preconditions: If \( n \) is positive, \( \text{ranges}::\text{distance}(\text{current}_-, \text{end}_-) > \text{stride}_-\ast(\text{n} \ast 1) \) is true.

[Note 1: If \( n \) is negative, the Effects paragraph implies a precondition. — end note]

Effects: Equivalent to:
if (n > 0) {
    ranges::advance(current_, stride_ * (n - 1));
    missing_ = ranges::advance(current_, stride_, end_);
} else if (n < 0) {
    ranges::advance(current_, stride_ * n + missing_);
    missing_ = 0;
} 
return *this;

constexpr iterator& operator-=(difference_type x) 
    requires random_access_range<Base>;

Effects: Equivalent to: return *this += -x;

friend constexpr bool operator==(const iterator& x, default_sentinel_t);

Returns: x.current_ == x.end_.

friend constexpr bool operator==(const iterator& x, const iterator& y) 
    requires equality_comparable<iterator_t<Base>>;

Returns: x.current_ == y.current_.

friend constexpr bool operator<(const iterator& x, const iterator& y) 
    requires random_access_range<Base>;

Returns: x.current_ < y.current_.

friend constexpr bool operator>(const iterator& x, const iterator& y) 
    requires random_access_range<Base>;

Effects: Equivalent to: return y < x;

friend constexpr bool operator<=(const iterator& x, const iterator& y) 
    requires random_access_range<Base>;

Effects: Equivalent to: return !(y < x);

requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
r += n;
return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)
requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

Returns: Let \( N \) be \((x.current_ - y.current_). \)
- If \( Base \) models forward_range, \((N + x.missing_ - y.missing_) / x.stride_. \)
- Otherwise, if \( N \) is negative, \(-\text{div-ceil}(-N, x.stride_). \)
- Otherwise, \(\text{div-ceil}(N, x.stride_). \)

friend constexpr difference_type operator-(default_sentinel_t y, const iterator& x)
requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;

Returns: \(\text{div-ceil}(x.end_ - x.current_, x.stride_). \)

friend constexpr range_rvalue_reference_t<Base> iter_move(const iterator& i)
noexcept(noexcept(ranges::iter_move(i.current_));

Effects: Equivalent to: return ranges::iter_move(i.current_);

friend constexpr range_rvalue_reference_t<Base> iter_move(const iterator& x, const iterator& y)
noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
requires indirectly_swappable<iterator_t<Base>>;

Effects: Equivalent to: ranges::iter_swap(x.current_, y.current_);

26.7.32 Cartesian product view

26.7.32.1 Overview
cartesian_product_view takes any non-zero number of ranges \( n \) and produces a view of tuples calculated by the \( n \)-ary cartesian product of the provided ranges.

The name views::cartesian_product denotes a customization point object (16.3.3.3.5). Given a pack of subexpressions \( Es \), the expression views::cartesian_product(\( Es \)) is expression-equivalent to

- views::single(tuple()) if \( Es \) is an empty pack,
- otherwise, cartesian_product_view<views::all_t<decltype((Es))>...>(Es...).

[Example 1:
vector<int> v { 0, 1, 2 };]
for (auto&& [a, b, c] : views::cartesian_product(v, v, v)) {
    cout << a << ' ' << b << ' ' << c << '
';
}
// The above prints
// 0 0 0
// 0 0 1
// 0 0 2
// 0 1 0
// 0 1 1
// ...—end example]

26.7.32.2 Class template cartesian_product_view

namespace std::ranges {

    template<bool Const, class First, class... Vs>
    concept cartesian-product-is-random-access = // exposition only
        (random_access_range<maybe-const<Const, First>> && ... &&
         (random_access_range<maybe-const<Const, Vs>>

        if constexpr (common_range<R>) {
            return ranges::end(r);
        } else {
            return ranges::begin(r) + ranges::distance(r);
        }
    }

    template<input_range First, forward_range... Vs>
    requires (view<First> && ... && view<Vs>)
    class cartesian_product_view : public view_interface<cartesian_product_view<First, Vs...>> {    // exposition only
        private:
            tuple<First, Vs...> bases_;  // exposition only
            // 26.7.32.3, class template cartesian_product_view::iterator
            template<bool Const> class iterator;    // exposition only
}
public:
constexpr cartesian_product_view() = default;
constexpr explicit cartesian_product_view(First first_base, Vs... bases);

constexpr iterator<false> begin()
  requires (!simple-view<First> || ... || !simple-view<Vs>);
constexpr iterator<true> begin() const
  requires (range<const First> && ... && range<const Vs>);

constexpr iterator<false> end()
  requires (((!simple-view<First> || ... || !simple-view<Vs>) &&
              cartesian-product-is-common<First, Vs...>);
constexpr iterator<true> end() const
  requires cartesian-product-is-common<const First, const Vs...>;
constexpr default_sentinel_t end() const noexcept;

constexpr see below size()
  requires cartesian-product-is-sized<First, Vs...>;
constexpr see below size() const
  requires cartesian-product-is-sized<const First, const Vs...>;
};

template<class... Vs>
cartesian_product_view(Vs&&...) -> cartesian_product_view<views::all_t<Vs>...>;

constexpr explicit cartesian_product_view(First first_base, Vs... bases);

Effects: Initializes bases_ with std::move(first_base), std::move(bases)....

constexpr iterator<false> begin()
  requires (!simple-view<First> || ... || !simple-view<Vs>);

Effects: Equivalent to:
  return iterator<false>(*this, tuple-transform(ranges::begin, bases_));

constexpr iterator<true> begin() const
  requires (range<const First> && ... && range<const Vs>);

Effects: Equivalent to:
  return iterator<true>(*this, tuple-transform(ranges::begin, bases_));

constexpr iterator<false> end()
  requires (!simple-view<First> || ... || !simple-view<Vs>)
    && cartesian-product-is-common<First, Vs...>;
constexpr iterator<true> end() const
  requires cartesian-product-is-common<const First, const Vs...>;

4 Let:
   — is-const be true for the const-qualified overload, and false otherwise;
   — is-empty be true if the expression ranges::empty(rng) is true for any rng among the underlying ranges except the first one and false otherwise; and
   — begin-or-first-end(rng) be expression-equivalent to is-empty ? ranges::begin(rng) : cartesian-common-arg-end(rng) if rng is the first underlying range and ranges::begin(rng) otherwise.

Effects: Equivalent to:
  iterator<is-const> it(*this, tuple-transform(
    [](auto& rng){ return begin-or-first-end(rng); }, bases_));
  return it;

constexpr default_sentinel_t end() const noexcept;

5 Returns: default_sentinel.
constexpr see below size();
requires cartesian-product-is-sized<First, Vs...>;
constexpr see below size() const
requires cartesian-product-is-sized<const First, const Vs...>;

The return type is an implementation-defined unsigned-integer-like type.

Recommended practice: The return type should be the smallest unsigned-integer-like type that is
sufficiently wide to store the product of the maximum sizes of all the underlying ranges, if such a type
exists.

Let p be the product of the sizes of all the ranges in bases_.

Preconditions: p can be represented by the return type.

Returns: p.

26.7.32.3 Class template cartesian_product_view::iterator

namespace std::ranges {
  template<input_range First, forward_range... Vs>
    requires (view<First> && ... && view<Vs>)
  template<bool Const>
    class cartesian_product_view<First, Vs...>::iterator {
public:

}

1 iterator::iterator_concept is defined as follows:
    (1.1) — If cartesian-product-is-random-access<Const, First, Vs...> is modeled, then iterator_concept denotes random_access_iterator_tag.
    (1.2) — Otherwise, if cartesian-product-is-bidirectional<Const, First, Vs...> is modeled, then iterator_concept denotes bidirectional_iterator_tag.
    (1.3) — Otherwise, if maybe-const<Const, First> models forward_range, then iterator_concept denotes forward_iterator_tag.
    (1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 iterator::difference_type is an implementation-defined signed-integer-like type.

3 Recommended practice: iterator::difference_type should be the smallest signed-integer-like type that is sufficiently wide to store the product of the maximum sizes of all underlying ranges if such a type exists.

4 template<
    size_t N = sizeof...(Vs)
  >
  constexpr void next();

5 Effects: Equivalent to:

auto& it = std::get<N>(current_);
+it;
if constexpr (N > 0) {
  if (it == ranges::end(std::get<N>(parent_->bases_))) {
    it = ranges::begin(std::get<N>(parent_->bases_));
    next<N - 1>();}
template<
  size_t N = sizeof...(Vs)>
constexpr void prev();

Effects: Equivalent to:

auto& it = std::get<N>(current_);
if constexpr (N > 0) {
  if (it == ranges::begin(std::get<N>(parent_)->bases_)) {
    it = cartesian-common-arg-end(std::get<N>(parent_)->bases_);
    prev<N - 1>();
  }
} --it;

template<class Tuple>
constexpr difference_type distance-from(const Tuple& t) const;

Let:

(7.1) — scaled-size(N) be the product of static_cast<
difference_type>(ranges::size(std::get<N>(parent_)->bases_))
and scaled-size(N + 1) if N ≤ sizeof...(Vs), otherwise static_-
cast<
difference_type>(1);
(7.2) — scaled-distance(N) be the product of static_cast<
difference_type>(std::get<N>(current_) - std::get<N>(t))
and scaled-size(N + 1); and
(7.3) — scaled-sum be the sum of scaled-distance(N) for every integer
0 ≤ N ≤ sizeof...(Vs).

Preconditions: scaled-sum can be represented by difference_type.

Returns: scaled-sum.

constexpr iterator(Parent& parent, tuple<
  iterator_t<
    maybe-const<Const, First>>,
  iterator_t<
    maybe-const<Const, Vs>>...> current);

Effects: Initializes parent_ with addressof(parent) and current_ with
std::move(current).

constexpr iterator(iterator<!Const> i) requires Const &&
  (convertible_to<
    iterator_t<
      maybe-const<Const, First>> && ...
    && convertible_to<
      iterator_t<
        maybe-const<Const, Vs>>));

Effects: Initializes parent_ with i.parent_ and current_ with
std::move(i.current_).

constexpr auto operator*() const;

Effects: Equivalent to:

return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);

constexpr iterator operator++();

Effects: Equivalent to:

next();
return *this;

constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator operator++(int) requires forward_range<
  maybe-const<Const, First>>;

Effects: Equivalent to:

auto tmp = *this;
+++this;
return tmp;

constexpr iterator operator--();

requires cartesian-product-is-bidirectional<Const, First, Vs...>;

Effects: Equivalent to:

requires cartesian-product-is-bidirectional<Const, First, Vs...>;
Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type x)
requires cartesian-product-is-random-access<Const, First, Vs...>;
Let orig be the value of *this before the call.
Let ret be:
(18.1) If x > 0, the value of *this had next been called x times.
(18.2) Otherwise, if x < 0, the value of *this had prev been called -x times.
(18.3) Otherwise, orig.
Preconditions: x is in the range [ranges::distance(*this, ranges::begin(*parent_)),
ranges::distance(*this, ranges::end(*parent_))].
Effects: Sets the value of *this to ret.
Returns: *this.
Complexity: Constant.

constexpr iterator& operator-=(difference_type x)
requires cartesian-product-is-random-access<Const, First, Vs...>;
Effects: Equivalent to:
*this += -x;
return *this;

constexpr reference operator[](difference_type n) const
requires cartesian-product-is-random-access<Const, First, Vs...>;
Effects: Equivalent to: return *((*this) + n);
friend constexpr bool operator==(const iterator& x, const iterator& y)
requires equality_comparable<iterator_t<maybe-const<Const, First>>>;
Effects: Equivalent to: return x.current_ == y.current_;
friend constexpr bool operator==(const iterator& x, default_sentinel_t);
Returns: true if std::get<i>(x.current_) == ranges::end(std::get<i>(x.parent_->bases_))
is true for any integer 0 ≤ i ≤ sizeof...(Vs); otherwise, false.
friend constexpr auto operator<=>(const iterator& x, const iterator& y)
requires all-random-access<Const, First, Vs...>;
Effects: Equivalent to: return x.current_ <=> y.current_;
friend constexpr iterator operator+(const iterator& x, difference_type y)
requires cartesian-product-is-random-access<Const, First, Vs...>;
Effects: Equivalent to: return iterator(x) += y;
friend constexpr iterator operator+(difference_type x, const iterator& y)
requires cartesian-product-is-random-access<Const, First, Vs...>;
Effects: Equivalent to: return iterator(x) += y;
friend constexpr iterator operator-(const iterator& x, difference_type y)
requires cartesian-product-is-random-access<Const, First, Vs...>;
Effects: Equivalent to: return iterator(x) -= y;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
requires cartesian-is-sized-sentinel<Const, iterator_t, First, Vs...>;

Effects: Equivalent to: return x.distance-from(y.current_);

friend constexpr difference_type operator-(const iterator& i, default_sentinel_t)
requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;

Effects: Equivalent to: return i.distance-from(end-tuple);

friend constexpr difference_type operator-(default_sentinel_t s, const iterator& i)
requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;

Effects: Equivalent to: return -(i - s);

friend constexpr auto iter_move(const iterator& i) noexcept;

Effects: Equivalent to: return tuple-transform(ranges::iter_move, i.current_);

Remarks: The exception specification is equivalent to the logical AND of the following expressions:
— noexcept(ranges::iter_move(std::get<i>(l.current_))) for every integer 0 ≤ i ≤ sizeof...(Vs),
— is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<Const, T>>>
for every type T in First, Vs...

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept;
requires (indirectly_swappable<iterator_t<maybe-const<Const, First>>> && ... && indirectly_swappable<iterator_t<maybe-const<Const, Vs>>>);

Effects: For every integer 0 ≤ i ≤ sizeof...(Vs), performs:
ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))

Remarks: The exception specification is equivalent to the logical AND of the following expressions:
— noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))) for every integer 0 ≤ i ≤ sizeof...(Vs).

26.8 Range generators

26.8.1 Overview

Class template generator presents a view of the elements yielded by the evaluation of a coroutine.
A generator generates a sequence of elements by repeatedly resuming the coroutine from which it was
returned. Elements of the sequence are produced by the coroutine each time a co_yield statement is
evaluated. When the co_yield statement is of the form co_yield elements_of(r), each element of the
range r is successively produced as an element of the sequence.

[Example 1:]
generator<int> ints(int start = 0) {
while (true)
  co_yield start++;
}

do f() {
  for (auto i : ints() | views::take(3))
    cout << i << ' ';   // prints 0 1 2
}
— end example]

}

1 Mandates:
(1.1) — If Allocator is not void, allocator_traits<Allocator>::pointer is a pointer type.
(1.2) — value is a cv-unqualified object type.
(1.3) — reference is either a reference type, or a cv-unqualified object type that models copy_constructible.
(1.4) — Let RRef denote remove_reference_t<reference&&> if reference is a reference type, and reference otherwise. Each of:
    (1.4.1) — common_reference_with<reference&&, value&>,
    (1.4.2) — common_reference_with<reference&&, RRef&&>, and
    (1.4.3) — common_reference_with<RRef&&, const value&

is modeled.

[Note 1: These requirements ensure the exposition-only iterator type can model indirectly_readable and thus input_iterator. — end note]
If Allocator is not void, it shall meet the Cpp17Allocator requirements.

Specializations of generator model view and input_range.

The behavior of a program that adds a specialization for generator is undefined.

### 26.8.4 Members

```cpp
generator(generator&& other) noexcept;
```

**Effects**: Initializes coroutine_ with exchange(other.coroutine_, {}) and active_ with exchange(other.active_, nullptr).

[Note 1: Iterators previously obtained from other are not invalidated; they become iterators into *this. — end note]

```cpp
~generator();
```

**Effects**: Equivalent to:

```cpp
default_sentinel_t end() const noexcept;
```

**Returns**: default_sentinel.

### 26.8.5 Class generator::promise_type

```cpp
namespace std {
    template<class Ref, class V, class Allocator>
    class generator<Ref, V, Allocator>::promise_type {
    public:
        generator get_return_object() noexcept;
        suspend_always initial_suspend() const noexcept { return {}; }
        auto final_suspend() noexcept;
        suspend_always yield_value(yielded val) noexcept;
        auto yield_value(const remove_reference_t<yielded>& lval) requires is_rvalue_reference_v<yielded> &&
            constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded>&>;
    }
}
```
template<class R2, class V2, class Alloc2, class Unused>
requires same_as<typename generator<R2, V2, Alloc2>::yielded, yielded>
auto yield_value(ranges::elements_of<generator<R2, V2, Alloc2>&&, Unused> g) noexcept;

template<ranges::input_range R, class Alloc>
requires convertible_to<ranges::range_reference_t<R>, yielded>
auto yield_value(ranges::elements_of<R, Alloc> r);

void await_transform() = delete;

void return_void() const noexcept {}
void unhandled_exception();

void* operator new(size_t size)
requires same_as<Allocator, void> || default_initializable<Allocator>;

template<class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);

template<class This, class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc,
const Args&...);

void operator delete(void* pointer, size_t size) noexcept;

private:
  add_pointer_t<yielded> value_ = nullptr; // exposition only
  exception_ptr except_; // exposition only
};

generator get_return_object() noexcept;

Returns: A generator object whose member coroutine_ is coroutine_handle<promise_type>::
from_promise(*this), and whose member active_ points to an empty stack.

auto final_suspend() noexcept;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of
*active_ of some generator object x. This function is called by that coroutine upon reaching its final
suspend point (9.5.4).

Returns: An awaitable object of unspecified type (7.6.2.4) whose member functions arrange for the
calling coroutine to be suspended, pop the coroutine handle from the top of *x.active_ and resume
execution of the coroutine referred to by x.active_ ->top() if *x.active_ is not empty. If it is empty,
control flow returns to the current coroutine caller or resumer (9.5.4).

suspend_always yield_value(yielded val) noexcept;

Effects: Equivalent to value_ = addressof(val).

Returns: {}.

auto yield_value(const remove_reference_t<yielded>& lval)
requires is_rvalue_reference_v<yielded> &&
constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded>&>;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of
*active_ of some generator object.

Returns: An awaitable object of an unspecified type (7.6.2.4) that stores an object of type remove_-
cvref_t<yielded> direct-non-list-initialized with lval, whose member functions arrange for value_ to
point to that stored object and then suspend the coroutine.

Throws: Any exception thrown by the initialization of the stored object.
`Remarks:` A `yield-expression` that calls this function has type `void` (7.6.17).

```cpp
template<class R2, class V2, class Alloc2, class Unused>
requires same_as<typename generator<R2, V2, Alloc2>&&, Unused> g) noexcept;
```

`Preconditions:` A handle referring to the coroutine whose promise object is `*this` is at the top of `*active_` of some generator object `x`. The coroutine referred to by `g.range.coroutine_` is suspended at its initial suspend point.

`Returns:` An awaitable object of an unspecified type (7.6.2.4) into which `g.range` is moved, whose `member await_ready` returns `false`, whose member `await_suspend` pushes `g.range.coroutine_` into `*x.active_` and resumes execution of the coroutine referred to by `g.range.coroutine_`, and whose member `await_resume` evaluates `rethrow_exception(except_)` if `bool(except_)` is true. If `bool(except_)` is false, the `await_resume` member has no effects.

`Remarks:` A `yield-expression` that calls this function has type `void` (7.6.17).

```cpp
template<ranges::input_range R, class Alloc>
requires convertible_to<ranges::range_reference_t<R>, yielded>
auto yield_value(ranges::elements_of<R, Alloc> r);
```

`Effects:` Equivalent to:

```cpp
auto nested = [] (allocator_arg_t, Alloc, ranges::iterator_t<R> i, ranges::sentinel_t<R> s)
    -> generator<yielded, ranges::range_value_t<R>, Alloc> {
        for (; i != s; ++i) {
            co_yield static_cast<yielded>(*i);
        }
    };
return yield_value(ranges::elements_of(nested(r.allocator, ranges::begin(r.range), ranges::end(r.range))));
```

`Note 1:` A `yield-expression` that calls this function has type `void` (7.6.17). — end note

```cpp
void unhandled_exception();
```

`Preconditions:` A handle referring to the coroutine whose promise object is `*this` is at the top of `*active_` of some generator object `x`.

`Effects:` If the handle referring to the coroutine whose promise object is `*this` is the sole element of `*x.active_`, equivalent to `throw`, otherwise, assigns `current_exception()` to `except_`.

```cpp
void* operator new(size_t size)
requires same_as<Allocator, void> || default_initializable<Allocator>;
```

```cpp
template<class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);
```

```cpp
template<class This, class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc, const Args&...);
```

Let `A` be

- `Alloc`, if it is not `void`,
- `Alloc` for the overloads with a template parameter `Alloc`, or
- `allocator<void>` otherwise.

Let `B` be `allocator_traits<A>::template rebind_alloc<U>` where `U` is an unspecified type whose size and alignment are both `__STDCPP_DEFAULT_NEW_ALIGNMENT__`.

`Mandates:` `allocator_traits<B>::pointer` is a pointer type.

`Effects:` Initializes an allocator `b` of type `B` with `A(alloc)`, for the overloads with a function parameter `alloc`, and with `A()` otherwise. Uses `b` to allocate storage for the smallest array of `U` sufficient to
provide storage for a coroutine state of size \(size\), and unspecified additional state necessary to ensure that `operator delete` can later deallocate this memory block with an allocator equal to \(b\).

**Returns:** A pointer to the allocated storage.

```cpp
void operator delete(void* pointer, size_t size) noexcept;
```

**Preconditions:** `pointer` was returned from an invocation of one of the above overloads of `operator new` with a `size` argument equal to \(size\).

**Effects:** Deallocates the storage pointed to by `pointer` using an allocator equivalent to that used to allocate it.

### § 26.8.6  Class `generator::iterator` [coro.generator.iterator]

```cpp
namespace std {
    template<class Ref, class V, class Allocator>
    class generator<Ref, V, Allocator>::iterator {
        public:
            using value_type = value;
            using difference_type = ptrdiff_t;

            iterator(iterator&& other) noexcept;
            iterator& operator=(iterator&& other) noexcept;
            reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);
            iterator& operator++();
            void operator++(int);

            friend bool operator==(const iterator& i, default_sentinel_t);

        private:
            coroutine_handle<promise_type> coroutine_; // exposition only
        }
    }
```

**Effects:** Initializes `coroutine_` with `exchange(other.coroutine_, {})`.

```cpp
iterator& operator=(iterator&& other) noexcept;
```

**Effects:** Equivalent to `coroutine_ = exchange(other.coroutine_, {})`.

**Returns:** `*this`.

```cpp
reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);
```

**Preconditions:** For some `generator` object \(x\), `coroutine_` is in `*x.active_` and \(x.active_\)->top() refers to a suspended coroutine with promise object \(p\).

**Effects:** Equivalent to: `return static_cast<reference>(*p.value_)`;

```cpp
iterator& operator++();
```

**Preconditions:** For some `generator` object \(x\), `coroutine_` is in `*x.active_`.

**Effects:** Equivalent to `x.active_\)->top().resume()`.

**Returns:** `*this`.

```cpp
void operator++(int);
```

**Effects:** Equivalent to `+++this`.

```cpp
friend bool operator==(const iterator& i, default_sentinel_t);
```

**Effects:** Equivalent to: `return i.coroutine_.done();`
27 Algorithms library

27.1 General

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 24) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 93.

Table 93 — Algorithms library summary

27.2 Algorithms requirements

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

The entities defined in the std::ranges namespace in this Clause are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the postfix-expression in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

[Example 1:]

```cpp
global foo() {
    using namespace std::ranges;
    std::vector<int> vec{1, 2, 3};
    find(begin(vec), end(vec), 2);  // #1
}
```

The function call expression at #1 invokes std::ranges::find, not std::find, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::find is more specialized (13.7.7.3) than std::ranges::find since the former requires its first two parameters to have the same type. — end example]

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, where the template parameters are not constrained, the names of template parameters are used to express type requirements.

1. If an algorithm’s Effects element specifies that a value pointed to by any iterator passed as an argument is modified, then the type of that argument shall meet the requirements of a mutable iterator (25.3).
2. If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall meet the Cpp17InputIterator requirements (25.3.5.3).
3. If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall meet the Cpp17OutputIterator requirements (25.3.5.4).
4. If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, ForwardIterator2, or NoThrowForwardIterator, the template argument shall meet the Cpp17ForwardIterator requirements.
requirements (25.3.5.5) if it is required to be a mutable iterator, or model forward_iterator (25.3.4.11) otherwise.

(4.5) — If an algorithm’s template parameter is named NoThrowForwardIterator, the template argument is also required to have the property that no exceptions are thrown from increment, assignment, or comparison of, or indirection through, valid iterators.

(4.6) — If an algorithm’s template parameter is named BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the template argument shall meet the Cpp17BidirectionalIterator requirements (25.3.5.6) if it is required to be a mutable iterator, or model bidirectional_iterator (25.3.4.12) otherwise.

(4.7) — If an algorithm’s template parameter is named RandomAccessIterator, RandomAccessIterator1, or RandomAccessIterator2, the template argument shall meet the Cpp17RandomAccessIterator requirements (25.3.5.7) if it is required to be a mutable iterator, or model random_access_iterator (25.3.4.13) otherwise.

[Note 1: These requirements do not affect iterator arguments that are constrained, for which iterator category and mutability requirements are expressed explicitly. — end note]

Both in-place and copying versions are provided for certain algorithms. When such a version is provided for algorithm it is called algorithm_copy. Algorithms that take predicates end with the suffix _if (which follows the suffix _copy).

When not otherwise constrained, the Predicate parameter is used whenever an algorithm expects a function object (22.10) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as true. If an algorithm takes Predicate pred as its argument and first as its iterator argument with value type T, the expression pred(*first) shall be well-formed and the type decltype(pred(*first)) shall model boolean-testable (18.5.2). The function object pred shall not apply any non-constant function through its argument. Given a glvalue u of type (possibly const) T that designates the same object as *first, pred(u) shall be a valid expression that is equal to pred(*first).

When not otherwise constrained, the BinaryPredicate parameter is used whenever an algorithm expects a function object that, when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type T when T is part of the signature, returns a value testable as true. If an algorithm takes BinaryPredicate binary_pred as its argument and first1 and first2 as its iterator arguments with respective value types T1 and T2, the expression binary_pred(*first1, *first2) shall be well-formed and the type decltype(binary_pred(*first1, *first2)) shall model boolean-testable. Unless otherwise specified, BinaryPredicate always takes the first iterator’s value_type as its first argument, that is, in those cases when T value is part of the signature, the expression binary_pred(*first1, value) shall be well-formed and the type decltype(binary_pred(*first1, value)) shall model boolean-testable. binary_pred shall not apply any non-constant function through any of its arguments. Given a glvalue u of type (possibly const) T1 that designates the same object as *first1, and a glvalue v of type (possibly const) T2 that designates the same object as *first2, binary_pred(u, *first2), binary_pred(*first1, v), and binary_pred(u, v) shall each be a valid expression that is equal to binary_pred(*first1, *first2), and binary_pred(u, value) shall be a valid expression that is equal to binary_pred(*first1, value).

The parameters UnaryOperation, BinaryOperation, BinaryOperation1, and BinaryOperation2 are used whenever an algorithm expects a function object (22.10).

[Note 2: Unless otherwise specified, algorithms that take function objects as arguments can copy those function objects freely. If object identity is important, a wrapper class that points to a non-copied implementation object such as reference_wrapper<T> (22.10.6), or some equivalent solution, can be used. — end note]

When the description of an algorithm gives an expression such as *first == value for a condition, the expression shall evaluate to either true or false in boolean contexts.

In the description of the algorithms, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of a + n are the same as those of

```
auto tmp = a;
for (; n < 0; ++n) --tmp;
for (; n > 0; --n) ++tmp;
return tmp;
```
Similarly, operator - is used for some combinations of iterators and sentinel types for which it does not have to be defined. If \([a, b)\) denotes a range, the semantics of \(b - a\) in these cases are the same as those of

\[
\text{iter_difference_t<decltype(a)> } n = 0;
\]

for (auto \(t = a; \, t != b; \, ++t\) ++n;

return n;

and if \([b, a)\) denotes a range, the same as those of

\[
\text{iter_difference_t<decltype(b)> } n = 0;
\]

for (auto \(t = b; \, t != a; \, ++t\) --n;

return n;

12 In the description of the algorithms, given an iterator \(a\) whose difference type is \(D\), and an expression \(n\) of integer-like type other than \(cv\ D\), the semantics of \(a + n\) and \(a - n\) are, respectively, those of \(a + D(n)\) and \(a - D(n)\).

13 In the description of algorithm return values, a sentinel value \(s\) denoting the end of a range \([i, s)\) is sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator using \(\text{ranges::next}(i, s)\).

14 Overloads of algorithms that take \textit{range} arguments (26.4.2) behave as if they are implemented by calling \textit{ranges::begin} and \textit{ranges::end} on the \textit{range}(s) and dispatching to the overload in namespace \textit{ranges} that takes separate iterator and sentinel arguments.

15 The well-formedness and behavior of a call to an algorithm with an explicitly-specified template argument list is unspecified, except where explicitly stated otherwise.

\[\text{Note 3: Consequently, an implementation can declare an algorithm with different template parameters than those presented. — end note}\]

27.3 Parallel algorithms [algorithms.parallel]

27.3.1 Preamble [algorithms.parallel.defns]

1 Subclause 27.3 describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

2 A \textit{parallel algorithm} is a function template listed in this document with a template parameter named \textit{ExecutionPolicy}.

3 Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

\begin{enumerate}
\item All operations of the categories of the iterators or \textit{mdspan} types that the algorithm is instantiated with.
\item Operations on those sequence elements that are required by its specification.
\item User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
\item Operations on those function objects required by the specification.
\end{enumerate}

\[\text{Note 1: See 27.2. — end note}\]

These functions are herein called \textit{element access functions}.

\[\text{Example 1: The } \texttt{sort} \text{ function may invoke the following element access functions:}\]

\begin{enumerate}
\item Operations of the random-access iterator of the actual template argument (as per 25.3.5.7), as implied by the name of the template parameter \textit{RandomAccessIterator}.
\item The \texttt{swap} function on the elements of the sequence (as per the preconditions specified in 27.8.2.1).
\item The user-provided \texttt{Compare} function object.
\end{enumerate}

\[\text{— end example}\]

4 A standard library function is \textit{vectorization-unsafe} if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function.

\[\text{Note 2: Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. — end note}\]

\[\text{Example 2:}\]

\[
\text{int } x = 0;
\]
The above program may result in two consecutive calls to `m.lock()` on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution.

—end example

### 27.3.2 Requirements on user-provided function objects

Unless otherwise specified, function objects passed into parallel algorithms as objects of type `Predicate`, `BinaryPredicate`, `Compare`, `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, `BinaryOperation2`, `BinaryDivideOp`, and the operators used by the analogous overloads to these parallel algorithms that are formed by an invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

### 27.3.3 Effect of execution policies on algorithm execution

Parallel algorithms have template parameters named `ExecutionPolicy` (22.12) which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element access functions.

1. If an object is modified by an element access function, the algorithm will perform no other unsynchronized accesses to that object. The modifying element access functions are those which are specified as modifying the object.

   [Note 1: For example, `swap`, `++`, `--`, `@=`, and assignments modify the object. For the assignment and `@=` operators, only the left argument is modified. —end note]

2. Unless otherwise stated, implementations may make arbitrary copies of elements (with type `T`) from sequences where `is_trivially_copy_constructible_v<T>` and `is_trivially_destructible_v<T>` are true.

   [Note 2: This implies that user-supplied function objects cannot rely on object identity of arguments for such input sequences. If object identity of the arguments to these function objects is important, a wrapping iterator that returns a non-copied implementation object such as `reference_wrapper<T>` (22.10.6), or some equivalent solution, can be used. —end note]

3. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::sequenced_policy` all occur in the calling thread of execution.

   [Note 3: The invocations are not interleaved; see 6.9.1. —end note]

4. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::unsequenced_policy` are permitted to execute in an unordered fashion in the calling thread of execution, unsequenced with respect to one another in the calling thread of execution.

   [Note 4: This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another. —end note]

The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an execution `::unsequenced_policy` algorithm.

[Note 5: Because `::unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. —end note]

5. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_policy` are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by `thread` (33.4.3) or `jthread` (33.4.4) provide concurrent forward progress guarantees (6.9.2.3), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing in the same thread of execution are indeterminately sequenced with respect to each other.

   [Note 6: It is the caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. —end note]
Example 1:

```cpp
int a[] = {0,1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int i) {
    v.push_back(i*2+1);    // incorrect: data race
});
```

The program above has a data race because of the unsynchronized access to the container v. — end example

Example 2:

```cpp
std::atomic<int> x{0};
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    x.fetch_add(1, std::memory_order::relaxed);
    // spin wait for another iteration to change the value of x
    while (x.load(std::memory_order::relaxed) == 1) {}        // incorrect: assumes execution order
});
```

The above example depends on the order of execution of the iterations, and will not terminate if both iterations are executed sequentially on the same thread of execution. — end example

Example 3:

```cpp
int x = 0;
std::mutex m;
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    std::lock_guard<mutex> guard(m);
    ++x;
});
```

The above example synchronizes access to object x ensuring that it is incremented correctly. — end example

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `std::execution::parallel_unsequenced_policy` are permitted to execute in an unordered fashion in unspecified threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees.

Note 7: This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another. — end note

The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an `std::execution::parallel_unsequenced_policy` algorithm.

Note 8: Because `std::execution::parallel_unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note

Note 9: The semantics of invocation with `std::execution::unsequenced_policy`, `std::execution::parallel_policy`, or `std::execution::parallel_unsequenced_policy` allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation, e.g., due to lack of resources. — end note

If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

9.1 — temporarily block with forward progress guarantee delegation (6.9.2.3) on the completion of these library-managed threads of execution, or

9.2 — eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished.

Note 10: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. — end note

The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.
27.3.4 Parallel algorithm exceptions

During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a bad_alloc exception.

During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the ExecutionPolicy.

27.3.5 ExecutionPolicy algorithm overloads

Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named ExecutionPolicy, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type ExecutionPolicy&&, which is the first function parameter.

[Note 1: Not all algorithms have parallel algorithm overloads. — end note]

Unless otherwise specified, the semantics of ExecutionPolicy algorithm overloads are identical to their overloads without.

Unless otherwise specified, the complexity requirements of ExecutionPolicy algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most expr” or “exactly expr” and does not specify the number of assignments or swaps, and expr is not already expressed with \(O()\) notation, the complexity of the algorithm shall be \(O(expr)\).

Parallel algorithms shall not participate in overload resolution unless is_execution_policy_v<remove_cvref_t<ExecutionPolicy>> is true.

27.4 Header <algorithm> synopsis

```cpp
#include <initializer_list>   // see 17.10.2

27.6 Non-modifying sequence operations

27.6.1 All of

template<class InputIterator, class Predicate>
constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
            Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
         indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::all_of(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
         indirect_unary_predicate<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::all_of(R&& r, Pred pred, Proj proj = {});

Let $E$ be:

1. $\text{pred}(\ast i)$ for the overloads in namespace `std`;
2. $\text{invoke} (\text{pred}, \text{invoke} (\text{proj}, \ast i))$ for the overloads in namespace `ranges`.

Returns: `false` if $E$ is `false` for some iterator $i$ in the range `[first, last)`, and `true` otherwise.

Complexity: At most `last - first` applications of the predicate and any projection.
27.6.2 Any of

\( \text{template<class InputIterator, class Predicate> constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);} \)

\( \text{template<class ExecutionPolicy, class ForwardIterator, class Predicate> bool any_of(ExecutionPolicy&& \& exec, ForwardIterator first, ForwardIterator last, Predicate pred);} \)

\( \text{template<input_iterator I, sentinel_for<I> S, class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred> constexpr bool ranges::any_of(I first, S last, Pred pred, Proj proj = {});} \)

\( \text{template<input_range R, class Proj = identity, indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred> constexpr bool ranges::any_of(R&& r, Pred pred, Proj proj = {});} \)

1 Let \( E \) be:

\( \begin{align*}
\text{(1.1) & - pred(*i) for the overloads in namespace std;} \\
\text{(1.2) & invoke(pred, invoke(proj, *i)) for the overloads in namespace ranges.}
\end{align*} \)

2 \text{Returns: true if } E \text{ is true for some iterator } i \text{ in the range } [\text{first, last}), \text{ and false otherwise.}

3 \text{Complexity: At most last - first applications of the predicate and any projection.}

27.6.3 None of

\( \text{template<class InputIterator, class Predicate> constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);} \)

\( \text{template<class ExecutionPolicy, class ForwardIterator, class Predicate> bool none_of(ExecutionPolicy&& \& exec, ForwardIterator first, ForwardIterator last, Predicate pred);} \)

\( \text{template<input_iterator I, sentinel_for<I> S, class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred> constexpr bool ranges::none_of(I first, S last, Pred pred, Proj proj = {});} \)

\( \text{template<input_range R, class Proj = identity, indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred> constexpr bool ranges::none_of(R&& r, Pred pred, Proj proj = {});} \)

1 Let \( E \) be:

\( \begin{align*}
\text{(1.1) & - pred(*i) for the overloads in namespace std;} \\
\text{(1.2) & invoke(pred, invoke(proj, *i)) for the overloads in namespace ranges.}
\end{align*} \)

2 \text{Returns: false if } E \text{ is true for some iterator } i \text{ in the range } [\text{first, last}), \text{ and true otherwise.}

3 \text{Complexity: At most last - first applications of the predicate and any projection.}

27.6.4 Contains

\( \text{template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity> requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*> constexpr bool ranges::contains(I first, S last, const T& value, Proj proj = {});} \)

\( \text{template<input_range R, class T, class Proj = identity> requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*> constexpr bool ranges::contains(R&& r, const T& value, Proj proj = {});} \)

\( \text{template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity> requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2> constexpr bool ranges::contains_subrange(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});} \)

\( \text{template<forward_range R1, forward_range R2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity> requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2> constexpr bool ranges::contains_subrange(R1&& r1, R2&& r2, Pred pred = {});} \)
Returns: first2 == last2 || !ranges::search(first1, last1, first2, last2, pred, proj1, proj2).empty().

27.6.5 For each

template<class InputIterator, class Function>
constexpr Function for_each(InputIterator first, InputIterator last, Function f);  

Preconditions: Function meets the Cpp17MoveConstructible requirements (Table 31).
[Note 1: Function need not meet the requirements of Cpp17CopyConstructible (Table 32). — end note]
Effects: Applies f to the result of dereferencing every iterator in the range [first, last), starting from first and proceeding to last - 1.
[Note 2: If the type of first meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]
Returns: f.
Complexity: Applies f exactly last - first times.
Remarks: If f returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Function f);  

Preconditions: Function meets the Cpp17CopyConstructible requirements.
Effects: Applies f to the result of dereferencing every iterator in the range [first, last).
[Note 3: If the type of first meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]
Complexity: Applies f exactly last - first times.
Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.
[Note 4: Does not return a copy of its Function parameter, since parallelization often does not permit efficient state accumulation. — end note]

template<input_iterator I, sentinel_for<I> S, class Proj = identity, indirectly_unary_invocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_result<I, Fun> ranges::for_each(I first, S last, Fun f, Proj proj = {});  

template<input_range R, class Proj = identity, indirectly_unary_invocable<iterator_t<R>, Proj>> Fun>
constexpr ranges::for_each_result<borrowed_iterator_t<R>, Fun> ranges::for_each(R&& r, Fun f, Proj proj = {});  

Effects: Calls invoke(f, invoke(proj, *i)) for every iterator i in the range [first, last), starting from first and proceeding to last - 1.
[Note 5: If the result of invoke(proj, *i) is a mutable reference, f can apply non-constant functions. — end note]
Returns: {last, std::move(f)}.
Complexity: Applies f and proj exactly last - first times.
Remarks: If f returns a result, the result is ignored.
[Note 6: The overloads in namespace ranges require Fun to model copy_constructible. — end note]

template<class InputIterator, class Size, class Function>
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);  

Mandates: The type Size is convertible to an integral type (7.3.9, 11.4.8).
Preconditions: n >= 0 is true. Function meets the Cpp17MoveConstructible requirements.
[Note 7: Function need not meet the requirements of Cpp17CopyConstructible. — end note]
Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + n]\) in order.

[Note 8: If the type of \text{first} meets the requirements of a mutable iterator, \( f \) can apply non-constant functions through the dereferenced iterator. — end note]

Returns: \( \text{first} + n \).

Remarks: If \( f \) returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n, Function f);

Mandates: The type \text{Size} is convertible to an integral type (7.3.9, 11.4.8).

Preconditions: \( n \geq 0 \) is true. Function meets the Cpp17CopyConstructible requirements.

Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + n]\).

[Note 9: If the type of \text{first} meets the requirements of a mutable iterator, \( f \) can apply non-constant functions through the dereferenced iterator. — end note]

Returns: \( \text{first} + n \).

Remarks: If \( f \) returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.

template<input_iterator I, class Proj = identity, indirectly_unary_invocable<projected<I, Proj>> Fun>
cmplxx ranges::for_each_n(I first, iter_difference_t<I> n, Fun f, Proj proj = {});

Preconditions: \( n \geq 0 \) is true.

Effects: Calls \( \text{invoke}(f, \text{invoke}(\text{proj}, *i)) \) for every iterator \( i \) in the range \([\text{first}, \text{first} + n]\) in order.

[Note 10: If the result of \( \text{invoke}(<\text{proj}, *i) \) is a mutable reference, \( f \) can apply non-constant functions. — end note]

Returns: \{\text{first} + n, \text{std::move}(<f)}\}.

Remarks: If \( f \) returns a result, the result is ignored.

[Note 11: The overload in namespace \text{ranges} requires \text{Fun} to model copy_constructible. — end note]

27.6.6 Find

[alg.find]

template<class InputIterator, class T>
constexpr InputIterator find(InputIterator first, InputIterator last, const T& value); 

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& value);

template<class InputIterator, class Predicate>

```
template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2,
        BinaryPredicate pred);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
        ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2,
        BinaryPredicate pred);
```

```
template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
          class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
ranges::find_end(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                 Proj1 proj1 = {}, Proj2 proj2 = {});
```

```
template<forward_range R1, forward_range R2,
          class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
ranges::find_end(R1&& r1, R2&& r2, Pred pred = {},
                 Proj1 proj1 = {}, Proj2 proj2 = {});
```

1. Let:
   (1.1) `pred` be `equal_to{}` for the overloads with no parameter `pred`;
   (1.2) `E` be:
      (1.2.1) `pred(*(*(i + n), *(first2 + n)))` for the overloads in namespace `std`;
      (1.2.2) `invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n)))` for the overloads in namespace `ranges`;
   (1.3) `i` be `last1` if `[first2, last2)` is empty, or if `(last2 - first2) > (last1 - first1)` is true, or if there is no iterator in the range `[first1, last1 - (last2 - first2))` such that for every non-negative integer `n < (last2 - first2)`, `E` is true. Otherwise `i` is the last such iterator in `[first1, last1 - (last2 - first2))`.

2. Returns:
   (2.1) `i` for the overloads in namespace `std`.
   (2.2) `{i, i + (i == last1 ? 0 : last2 - first2)}` for the overloads in namespace `ranges`.

3. Complexity: At most `(last2 - first2) * (last1 - first1 - (last2 - first2) + 1)` applications of the corresponding predicate and any projections.

27.6.9 Find first
template<class InputIterator, class ForwardIterator>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1,
             ForwardIterator first2, ForwardIterator last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator, class ForwardIterator, class BinaryPredicate>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1,
             ForwardIterator first2, ForwardIterator last2,
             BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
             ForwardIterator1 first1, ForwardIterator1 last1,
             ForwardIterator2 first2, ForwardIterator2 last2,
             BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr I1
ranges::find_first_of(I1 first1, S1 last1, I2 first2, S2 last2,
                      Pred pred = {},
                      Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, forward_range R2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_iterator_t<R1>
ranges::borrowed_iterator_t<R1>
ranges::find_first_of(R1&& r1, R2&& r2,
                      Pred pred = {},
                      Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let \( E \) be:
   \[ \begin{align*}
   & (1.1) \quad \ast i == \ast j \text{ for the overloads with no parameter } \text{pred}; \\
   & (1.2) \quad \text{pred}(*i, *j) \neq \text{false} \text{ for the overloads with a parameter } \text{pred} \text{ and no parameter } \text{proj1}; \\
   & (1.3) \quad \text{bool(invoke(pred, invoke(proj1, *i), invoke(proj2, *j))) for the overloads with parameters } \text{pred} \text{ and } \text{proj1}.
   \end{align*} \]

2 **Effects:** Finds an element that matches one of a set of values.

3 **Returns:** The first iterator \( i \) in the range \([\text{first1}, \text{last1}]\) such that for some iterator \( j \) in the range \([\text{first2}, \text{last2}]\) \( E \) holds. Returns \( \text{last1} \) if \([\text{first2}, \text{last2}]\) is empty or if no such iterator is found.

4 **Complexity:** At most \((\text{last1-}\text{first1}) \ast (\text{last2-}\text{first2})\) applications of the corresponding predicate and any projections.

### 27.6.10 Adjacent find

template<class ForwardIterator>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last);
Let $E$ be:

1. $i == *(i + 1)$ for the overloads with no parameter $\text{pred}$;
2. $\text{pred}(i, *(i + 1))$ for the overloads with a parameter $\text{pred}$ and no parameter $\text{proj}$;
3. $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, i), \text{invoke}(\text{proj}, *(i + 1))))$ for the overloads with both parameters $\text{pred}$ and $\text{proj}$.

Returns: The first iterator $i$ such that both $i$ and $i + 1$ are in the range $[\text{first}, \text{last})$ for which $E$ holds. Returns $\text{last}$ if no such iterator is found.

Complexity: For the overloads with no $\text{ExecutionPolicy}$, exactly

$$\min((i - \text{first}) + 1, (\text{last} - \text{first}) - 1)$$

applications of the corresponding predicate, where $i$ is $\text{adjacent\_find}$'s return value. For the overloads with an $\text{ExecutionPolicy}$, $O(\text{last} - \text{first})$ applications of the corresponding predicate, and no more than twice as many applications of any projection.

### 27.6.11 Count

#### [alg.count]

template\(<\text{class ForwardIterator}, \text{class BinaryPredicate}>$
\begin{align*}
\text{constexpr ForwardIterator} & \quad \text{adjacent\_find(ForwardIterator first, ForwardIterator last, BinaryPredicate pred);} \\
\text{template\(<\text{class ExecutionPolicy, class ForwardIterator, class BinaryPredicate}>$

\text{template\(<\text{input\_range R, class T, class Proj = identity}>$
\begin{align*}
\text{requires indirect\_binary\_predicate\(\text{ranges::\text{x}\_\text{equal\_to}, projectted\(<\text{iterator\_t<R>}, Proj>, const T\*) constexpr range\_difference\_t\<R\> ranges::count(R\& r, const T\& value, Proj proj = {});} \\
\end{align*}
\end{align*}
\end{align*}
\end{align*}
\end{align*}
\end{align*}
\end{align*}
\end{align*}

§ 27.6.11
template<input_iterator I, sentinel_for<I> S, class Proj = identity, 
  indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr iter_difference_t<I>
ranges::count_if(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity, 
  indirect_unary_predicate<iterator_t<R>, Proj>> Pred>
constexpr range_difference_t<R>
ranges::count_if(R&& r, Pred pred, Proj proj = {});

Let $E$ be:

1. $\star i = \text{value}$ for the overloads with no parameter $\text{pred}$ or $\text{proj}$;
2. $\text{pred}(\star i) \neq \text{false}$ for the overloads with a parameter $\text{pred}$ but no parameter $\text{proj}$;
3. $\text{invoke}(\text{proj}, \star i) = \text{value}$ for the overloads with a parameter $\text{proj}$ but no parameter $\text{pred}$;
4. $\text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, \star i)))$ for the overloads with both parameters $\text{proj}$ and $\text{pred}$.

**Effects**: Returns the number of iterators $i$ in the range $[\text{first}, \text{last})$ for which $E$ holds.

**Complexity**: Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

### Mismatch

[alg.mismatch]

template<class InputIterator1, class InputIterator2>
constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1, 
          InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
pair<ForwardIterator1, ForwardIterator2>

template<input_range R1, input_range R2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr ranges::mismatch_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::mismatch(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2.
2 Let E be:

(2.1) !(*(first1 + n) == *(first2 + n)) for the overloads with no parameter pred:
(2.2) pred(*(first1 + n), *(first2 + n)) == false for the overloads with a parameter pred and
no parameter proj1;
(2.3) !invoke(pred, invoke(proj1, *(first1 + n)), invoke(proj2, *(first2 + n))) for the
overloads with both parameters pred and proj1.
3 Let N be min(last1 - first1, last2 - first2).
4 Returns: \{ first1 + n, first2 + n \}, where n is the smallest integer in [0, N) such that E holds,
or N if no such integer exists.
5 Complexity: At most N applications of the corresponding predicate and any projections.

27.6.13 Equal

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2,
class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2);
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
  class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2,
  BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
  class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::equal(I1 first1, S1 last1, I2 first2, S2 last2,
  Pred pred = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Pred = ranges::equal_to,
  class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::equal(R1&& r1, R2&& r2, Pred pred = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

Let:

(1.1) last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2;
(1.2) pred be equal_to{} for the overloads with no parameter pred;
(1.3) E be:

(1.3.1) pred(*i, *(first2 + (i - first1))) for the overloads with no parameter proj1;
(1.3.2) invoke(pred, invoke(proj1, *i), invoke(proj2, *(first2 + (i - first1)))) for
  the overloads with parameter proj1.

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if E holds
for every iterator i in the range [first1,last1). Otherwise, returns false.

Complexity: If
(3.1) the types of first1, last1, first2, and last2 meet the Cpp17RandomAccessIterator require-
  ments (25.3.5.7) and last1 - first1 != last2 - first2 for the overloads in namespace std;
(3.2) the types of first1, last1, first2, and last2 pairwise model sized_sentinel_for (25.3.4.8)
  and last1 - first1 != last2 - first2 for the first overload in namespace ranges,
(3.3) R1 and R2 each model sized_range and ranges::distance(r1) != ranges::distance(r2) for
  the second overload in namespace ranges,
then no applications of the corresponding predicate and each projection; otherwise,
(3.4) For the overloads with no ExecutionPolicy, at most min(last1 - first1, last2 - first2)
  applications of the corresponding predicate and any projections.
(3.5) For the overloads with an ExecutionPolicy, O(min(last1 - first1, last2 - first2)) appli-
  cations of the corresponding predicate.

27.6.14 Is permutation

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2);

template<class ForwardIterator1, class ForwardIterator2,
  class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, BinaryPredicate pred);

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
  class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

Let last2 be first2 + (last1 - first1) for the overloads with no parameter named last2, and let pred be equal_to{} for the overloads with no parameter pred.

Mandates: ForwardIterator1 and ForwardIterator2 have the same value type.

Preconditions: The comparison function is an equivalence relation.

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), beginning with ForwardIterator2 begin, such that equal(first1, last1, begin, pred) returns true; otherwise, returns false.

Complexity: No applications of the corresponding predicate if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2. Otherwise, exactly last1 - first1 applications of the corresponding predicate if equal(first1, last1, first2, last2, pred) would return true; otherwise, at worst \( \Theta(N^2) \), where \( N \) has the value last1 - first1.

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2,
         sentinel_for<I2> S2, class Proj1 = identity, class Proj2 = identity,
         indirect_equivalence_relation<projected<I1, Proj1>,
         projected<I2, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(I1 first1, S1 last1, I2 first2, S2 last2,
  Pred pred = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2,
         class Proj1 = identity, class Proj2 = identity,
         indirect_equivalence_relation<projected<iterator_t<R1>, Proj1>,
         projected<iterator_t<R2>, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(R1&& r1, R2&& r2, Pred pred = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), bounded by [pfirst, plast), such that ranges::equal(first1, last1, pfirst, plast, pred, proj1, proj2) returns true; otherwise, returns false.

Complexity: No applications of the corresponding predicate and projections if:

(7.1) — for the first overload,
  (7.1.1) — S1 and I1 model sized_sentinel_for<S1, I1>,
  (7.1.2) — S2 and I2 model sized_sentinel_for<S2, I2>, and
  (7.1.3) — last1 - first1 != last2 - first2;
(7.2) — for the second overload, R1 and R2 each model sized_range, and ranges::distance(r1) != ranges::distance(r2).

Otherwise, exactly last1 - first1 applications of the corresponding predicate and projections if ranges::equal(first1, last1, first2, last2, pred, proj1, proj2) would return true; otherwise, at worst \( \Theta(N^2) \), where \( N \) has the value last1 - first1.

27.6.15 Search

[alg.search]
template<class ForwardIterator1, class ForwardIterator2, 
class BinaryPredicate>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2, 
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
class BinaryPredicate>
ForwardIterator1
search(ExecutionPolicy&& exec, 
ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2, 
BinaryPredicate pred);

1 Returns: The first iterator \( i \) in the range \([\text{first1}, \text{last1} - (\text{last2} - \text{first2}))\) such that for every non-negative integer \( n \) less than \( \text{last2} - \text{first2} \) the following corresponding conditions hold: \( *(i + n) == *(\text{first2} + n) \), \( \text{pred}(*(i + n), *(\text{first2} + n)) \) != false. Returns \text{first1} if \([\text{first2}, \text{last2})\) is empty, otherwise returns \text{last1} if no such iterator is found.

2 Complexity: At most \((\text{last1} - \text{first1}) \times (\text{last2} - \text{first2})\) applications of the corresponding predicate.

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, 
sentinel_for<I2> S2, class Pred = ranges::equal_to, 
class Proj1 = identity, class Proj2 = identity>
constexpr subrange<I1>
ranges::search(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, 
Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2, class Pred = ranges::equal_to, 
class Proj1 = identity, class Proj2 = identity>
constexpr borrowed_subrange_t<R1>
ranges::search(R1&& r1, R2&& r2, Pred pred = {}, 
Proj1 proj1 = {}, Proj2 proj2 = {});

3 Returns:

\( (3.1) \) \{i, i + ((\text{last2} - \text{first2}))\}, where \( i \) is the first iterator in the range \([\text{first1}, \text{last1} - (\text{last2} - \text{first2}))\) such that for every non-negative integer \( n \) less than \( \text{last2} - \text{first2} \) the condition

\[
\text{bool}(\text{invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(\text{first2} + n))))}
\]

is true.

\( (3.2) \) Returns \{\text{last1}, \text{last1}\} if no such iterator exists.

4 Complexity: At most \((\text{last1} - \text{first1}) \times (\text{last2} - \text{first2})\) applications of the corresponding predicate and projections.
template<class ExecutionPolicy, class ForwardIterator, class Size, class T,  
class BinaryPredicate>
ForwardIterator
search_n(ExecutionPolicy&& exec,  
ForwardIterator first, ForwardIterator last,  
Size count, const T& value,  
BinaryPredicate pred);

Mandates: The type Size is convertible to an integral type (7.3.9, 11.4.8).

Returns: The first iterator i in the range [first, last-count) such that for every non-negative integer n less than count the following corresponding conditions hold: *(i + n) == value, pred(*((i + n)), value) != false. Returns last if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate.

template<forward_iterator I, sentinel_for<I> S, class T,  
class Pred = ranges::equal_to, class Proj = identity>
constexpr subrange<I>
ranges::search_n(I first, S last, iter_difference_t<I> count,  
const T& value, Pred pred = {}, Proj proj = {});  
constexpr subrange<iterator_t<R>, const T*, Pred, Proj>  
ranges::search_n(R&& r, range_difference_t<R> count,  
const T& value, Pred pred = {}, Proj proj = {});

Returns: {i, i + count} where i is the first iterator in the range [first, last - count) such that for every non-negative integer n less than count, the following condition holds: invoke(pred, invoke(proj, *(i + n)), value). Returns {last, last} if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate and projection.

template<class ForwardIterator, class Searcher>
constexpr ForwardIterator
search(ForwardIterator first, ForwardIterator last, const Searcher& searcher);

Effects: Equivalent to: return searcher(first, last).first;

Remarks: Searcher need not meet the Cpp17CopyConstructible requirements.

27.6.16 Starts with

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,  
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::starts_with(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},  
Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Pred = ranges::equal_to, class Proj1 = identity,  
class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::starts_with(R1&& r1, R2&& r2, Pred pred = {},  
Proj1 proj1 = {}, Proj2 proj2 = {});

Returns:
ranges::mismatch(std::move(first1), last1, std::move(first2), last2,  
pred, proj1, proj2).in2 == last2

27.6.17 Ends with

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,  
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires (forward_iterator<I1> || sized_sentinel_for<S1, I1>) &&  
(forward_iterator<I2> || sized_sentinel_for<S2, I2>) &&  
indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::ends_with(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}),
Let $N_1$ be $last_1 - first_1$ and $N_2$ be $last_2 - first_2$.

Returns: false if $N_1 < N_2$, otherwise

ranges::equal(std::move(first1) + (N1 - N2), last1, std::move(first2), last2,
pred, proj1, proj2)

template<input_range R1, input_range R2, class Pred = ranges::equal_to, class Proj1 = identity,
class Proj2 = identity>
requires (forward_range<R1> || sized_range<R1>) &&
(forward_range<R2> || sized_range<R2>) &&
indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::ends_with(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let $N_1$ be ranges::distance(r1) and $N_2$ be ranges::distance(r2).

Returns: false if $N_1 < N_2$, otherwise

ranges::equal(ranges::drop_view(ranges::ref_view(r1), N1 - N2), r2, pred, proj1, proj2)

27.6.18 Fold [alg.fold]

template<input_iterator I, sentinel_for<I> S, class T,
indirectly-binary-left-foldable<T, I> F>
constexpr auto ranges::fold_left(I first, S last, T init, F f);

template<input_range R, class T,
indirectly-binary-left-foldable<range_value_t<R>, iterator_t<R>> F>
constexpr auto ranges::fold_left(R&& r, T init, F f);

1 Returns:
ranges::fold_left_with_iter(std::move(first), last, std::move(init), f).value

template<input_iterator I, sentinel_for<I> S,
indirectly-binary-left-foldable<iter_value_t<I>, I> F>
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
constexpr auto ranges::fold_left_first(I first, S last, F f);

template<input_range R, indirectly-binary-left-foldable<iter_value_t<R>, range_value_t<R>, range_reference_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
constexpr auto ranges::fold_left_first(R&& r, F f);

2 Returns:
ranges::fold_left_first_with_iter(std::move(first), last, f).value

template<bidirectional_iterator I, sentinel_for<I> S, class T,
indirectly-binary-right-foldable<T, I> F>
constexpr auto ranges::fold_right(I first, S last, T init, F f);

template<bidirectional_range R, class T,
indirectly-binary-right-foldable<range_value_t<R>, iterator_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
constexpr auto ranges::fold_right(R&& r, T init, F f);

3 Effects: Equivalent to:

using U = decay_t<invoke_result_t<F&, iter_reference_t<I>, T>>;
if (first == last)
    return U(std::move(init));
I tail = ranges::next(first, last);
U accum = invoke(f, --tail, std::move(init));
while (first != tail)
    accum = invoke(f, --tail, std::move(accum));
return accum;

template<bidirectional_iterator I, sentinel_for<I> S,
indirectly-binary-right-foldable<iter_value_t<I>, I> F>
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
constexpr auto ranges::fold_right_last(I first, S last, F f);

template<bidirectional_range R, indirectly-binary-right-foldable<range_value_t<R>, range_reference_t<R, range_reference_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
```cpp
constexpr auto ranges::fold_right_last(R&& r, F f);

Let U be decltype(ranges::fold_right(first, last, iter_value_t<I>(*first), f)).

Effects: Equivalent to:
   if (first == last)
      return optional<U>();
   I tail = ranges::prev(ranges::next(first, std::move(last)));
   return optional<U>(in_place,
      ranges::fold_right(std::move(first), tail, iter_value_t<I>(*tail), std::move(f)));

template<input_iterator I, sentinel_for<I> S, class T, indirectly-binary-left-foldable<T, I> F>
constexpr see below ranges::fold_left_with_iter(I first, S last, T init, F f);

template<input_range R, class T, indirectly-binary-left-foldable<T, iterator_t<R>> F>
constexpr see below ranges::fold_left_with_iter(R&& r, T init, F f);

Let U be decay_t<invoke_result_t<F&, T, iter_reference_t<I>>>.

Effects: Equivalent to:
   if (first == last)
      return {std::move(first), U(std::move(init))};
   U accum = invoke(f, std::move(init), *first);
   for (++first; first != last; ++first)
      accum = invoke(f, std::move(accum), *first);
   return {std::move(first), std::move(accum)};

Remarks: The return type is fold_left_with_iter_result<I, U> for the first overload and fold_left_with_iter_result<borrowed_iterator_t<R>, U> for the second overload.

template<input_iterator I, sentinel_for<I> S, indirectly-binary-left-foldable<iter_value_t<I>, I> F>
requires constructible_from<iter_value_t<I>, iter_reference_t<I>>
constexpr see below ranges::fold_left_first_with_iter(I first, S last, F f);

template<input_range R, indirectly-binary-left-foldable<range_value_t<R>, iterator_t<R>> F>
requires constructible_from<range_value_t<R>, range_reference_t<R>>
constexpr see below ranges::fold_left_first_with_iter(R&& r, F f);

Let U be
decaytype(ranges::fold_left(std::move(first), last, iter_value_t<I>(*first), f))

Effects: Equivalent to:
   if (first == last)
      return {std::move(first), optional<U>()};
   optional<U> init(in_place, *first);
   for (++first; first != last; ++first)
      *init = invoke(f, std::move(*init), *first);
   return {std::move(first), std::move(init)};

Remarks: The return type is fold_left_first_with_iter_result<I, optional<U>> for the first overload and fold_left_first_with_iter_result<borrowed_iterator_t<R>, optional<U>> for the second overload.

27.7 Mutating sequence operations [alg.modifying.operations]

27.7.1 Copy [alg.copy]

template<class InputIterator, class OutputIterator>
constexpr OutputIterator copy(InputIterator first, InputIterator last,
   OutputIterator result);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::copy_result<I, O> ranges::copy(I first, S last, O result);
```

§ 27.7.1 1366
template<input_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::copy_result<borrowed_iterator_t<R>, O> ranges::copy(R&& r, O result);

Let \( N \) be \( \text{last} - \text{first} \).

Preconditions: \( \text{result} \) is not in the range \([\text{first}, \text{last})\).

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + N)\) starting from \( \text{first} \) and proceeding to \( \text{last} \). For each non-negative integer \( n < N \), performs \( *(\text{result} + n) = *(\text{first} + n) \).

Returns:
1. \( \text{result} + N \) for the overload in namespace std.
2. \( \{\text{last}, \text{result} + N\} \) for the overload in namespace ranges.

Complexity: Exactly \( N \) assignments.

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 copy(ExecutionPolicy&& policy,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

Preconditions: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) do not overlap.

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\). For each non-negative integer \( n < (\text{last} - \text{first}) \), performs \( *(\text{result} + n) = *(\text{first} + n) \).

Returns: \( \text{result} + (\text{last} - \text{first}) \).

Complexity: Exactly \( \text{last} - \text{first} \) assignments.

template<class InputIterator, class Size, class OutputIterator>
constexpr OutputIterator copy_n(InputIterator first, Size n,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class Size, class ForwardIterator2>
ForwardIterator2 copy_n(ExecutionPolicy&& exec,
ForwardIterator1 first, Size n,
ForwardIterator2 result);

template<input_iterator I, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::copy_n_result<I, O>
ranges::copy_n(I first, iter_difference_t<I> n, O result);

Let \( N \) be \( \max(0, n) \).

Mandates: The type \( \text{Size} \) is convertible to an integral type (7.3.9, 11.4.8).

Effects: For each non-negative integer \( i < N \), performs \( *(\text{result} + i) = *(\text{first} + i) \).

Returns:
1. \( \text{result} + N \) for the overload in namespace std.
2. \( \{\text{first} + N, \text{result} + N\} \) for the overload in namespace ranges.

Complexity: Exactly \( N \) assignments.

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2 copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
Let \( E \) be:

- (15.1) \( \text{bool}(\text{pred}(*i)) \) for the overloads in namespace `std`;
- (15.2) \( \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i))) \) for the overloads in namespace `ranges`,

and \( N \) be the number of iterators \( i \) in the range \([\text{first}, \text{last})\) for which the condition \( E \) holds.

Preconditions: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) do not overlap.

[Note 1: For the overload with an `ExecutionPolicy`, there might be a performance cost if `std::iterator_traits<ForwardIterator>::value_type` is not `Cpp17MoveConstructible` (Table 31). — end note]

Effects: Copies all of the elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) is true.

Returns:

- (18.1) \( \text{result} + N \) for the overloads in namespace `std`.
- (18.2) \( \{\text{last}, \text{result} + N\} \) for the overloads in namespace `ranges`.

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

27.7.2 Move

[alg.move]
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_movable<I, O>
constexpr ranges::move_result<I, O>
ranges::move(I first, S last, O result);

template<input_range R, weakly_incrementable O>
requires indirectly_movable<iterator_t<R>, O>
constexpr ranges::move_result<borrowed_iterator_t<R>, O>
ranges::move(R&& r, O result);

Let $E$ be
(1.1) $\text{std::move}(*(\text{first } + n))$ for the overload in namespace std;

(1.2) $\text{ranges::iter_move}$(\text{first } + n) for the overloads in namespace ranges.

Let $N$ be last - first.

Preconditions: result is not in the range $[\text{first}, \text{last})$.

Effects: Moves elements in the range $[\text{first}, \text{last})$ into the range $[\text{result}, \text{result} + N)$ starting from first and proceeding to last. For each non-negative integer $n < N$, performs $\ast(\text{result} + n) = E$.

Returns:
(4.1) $\text{result} + N$ for the overload in namespace std.

(4.2) $\{\text{last}, \text{result} + N\}$ for the overloads in namespace ranges.

Complexity: Exactly $N$ assignments.

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 move(ExecutionPolicy&& policy,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

Let $N$ be last - first.

Preconditions: The ranges $[\text{first}, \text{last})$ and $[\text{result}, \text{result} + N)$ do not overlap.

Effects: Moves elements in the range $[\text{first}, \text{last})$ into the range $[\text{result}, \text{result} + N)$. For each non-negative integer $n < N$, performs $\ast(\text{result} + n) = \text{std::move}(*(\text{first } + n))$.

Returns: result + $N$.

Complexity: Exactly $N$ assignments.

template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
move_backward(BidirectionalIterator1 first, BidirectionalIterator1 last,
BidirectionalIterator2 result);

template<bidirectional_iterator I1, sentinel_for<I1> S1, bidirectional_iterator I2>
requires indirectly_movable<I1, I2>
constexpr ranges::move_backward_result<I1, I2>
ranges::move_backward(I1 first, S1 last, I2 result);

Let $E$ be
(11.1) $\text{std::move}(*(\text{last } - n))$ for the overload in namespace std;

(11.2) $\text{ranges::iter_move}(\text{last } - n)$ for the overloads in namespace ranges.

Let $N$ be last - first.

Preconditions: result is not in the range $[\text{first}, \text{last}]$.

Effects: Moves elements in the range $[\text{first}, \text{last})$ into the range $[\text{result} - N, \text{result})$ starting from last - 1 and proceeding to first.\(^{215}\) For each positive integer $n \leq N$, performs $\ast(\text{result} - n) = E$.

\(^{215}\) $\text{move_backward}$ can be used instead of $\text{move}$ when last is in the range $[\text{result} - N, \text{result})$. 

\section{27.7.2}
27.7.3 Swap

Returns:

— \texttt{result - } \( N \) for the overload in namespace \texttt{std}.

— \{\texttt{last, result - } \( N \)\} for the overloads in namespace \texttt{ranges}.

Complexity: Exactly \( N \) assignments.

\begin{verbatim}
[alg.swap]
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator2
swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2); // freestanding

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
swap_ranges(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2>
requires indirectly_swappable<I1, I2>
constexpr ranges::swap_ranges_result<I1, I2>
ranges::swap_ranges(I1 first1, S1 last1, I2 first2, S2 last2);

template<input_range R1, input_range R2>
requires indirectly_swappable<iterator_t<R1>, iterator_t<R2>>
constexpr ranges::swap_ranges_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::swap_ranges(R1&& r1, R2&& r2);

Let:

— \( \texttt{last2} \) be \( \texttt{first2} + (\texttt{last1} - \texttt{first1}) \) for the overloads with no parameter named \texttt{last2};

— \( \texttt{M} \) be \( \min(\texttt{last1} - \texttt{first1}, \texttt{last2} - \texttt{first2}) \).

Preconditions: The two ranges \([\texttt{first1}, \texttt{last1})\) and \([\texttt{first2}, \texttt{last2})\) do not overlap. For the overloads in namespace \texttt{std}, \(*(\texttt{first1} + n)\) is swappable with (16.4.4.3) \(*(\texttt{first2} + n)\).

Effects: For each non-negative integer \( n < M \) performs:

— \texttt{swap} \((\texttt{first1} + n), \texttt{first2} + n)\) for the overloads in namespace \texttt{std};

— ranges::\texttt{iter_swap} \((\texttt{first1} + n, \texttt{first2} + n)\) for the overloads in namespace \texttt{ranges}.

Returns:

— \texttt{last2} for the overloads in namespace \texttt{std}.

— \{\texttt{first1} + \( M \), \texttt{first2} + \( M \)\} for the overloads in namespace \texttt{ranges}.

Complexity: Exactly \( M \) swaps.
\end{verbatim}

27.7.4 Transform

\begin{verbatim}[alg.transform]
template<class InputIterator, class OutputIterator,

requires indirectly_writable<I, const T&>
constexpr I ranges::replace_if(I first, S last, Pred pred, const T& new_value, Proj proj = {});

template<input_range R, class T, class Proj = identity,
    indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_writable<iterator_t<R>, const T&>
constexpr borrowed_iterator_t<R> ranges::replace_if(R&& r, Pred pred, const T& new_value, Proj proj = {});
\end{verbatim}

Let $E$ be

\begin{itemize}
  \item \((\text{true} \cdot \text{true}) \Rightarrow \text{false}) \text{ for } \text{replace};
  \item \((\text{true} \cdot \text{false}) \Rightarrow \text{true}) \text{ for } \text{replace_if};
  \item \((\text{true} \cdot \text{true}) \Rightarrow \text{false}) \text{ for } \text{ranges::replace};
  \item \((\text{true} \cdot \text{false}) \Rightarrow \text{false}) \text{ for } \text{ranges::replace_if}.
\end{itemize}

\text{Effects:} Assigns through every iterator $i$ in the range $[\text{result}, \text{result} + N)$ a new corresponding value equal to $E$.

\text{Returns:}

\begin{itemize}
  \item $\text{result} + N$ for the overloads defined in namespace std.
  \item $\{\text{first1} + N, \text{result} + N\}$ for unary transforms defined in namespace ranges.
  \item $\{\text{first1} + N, \text{first2} + N, \text{result} + N\}$ for binary transforms defined in namespace ranges.
\end{itemize}

\text{Complexity:} Exactly $N$ applications of op or binary_op, and any projections. This requirement also applies to the overload with an ExecutionPolicy.

\text{Remarks:} result may be equal to first1 or first2.
Mandates: new_value is writable (25.3.1) to first.

Effects: Substitutes elements referred by the iterator i in the range [first, last) with new_value, when E is true.

Returns: last for the overloads in namespace ranges.

Complexity: Exactly last - first applications of the corresponding predicate and any projection.

```cpp
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
replace_copy(InputIterator first, InputIterator last, OutputIterator result, const T& old_value, const T& new_value);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
replace_copy(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, const T& old_value, const T& new_value);
```

```cpp
template<class InputIterator, class OutputIterator, class Predicate, class T>
constexpr OutputIterator
replace_copy_if(InputIterator first, InputIterator last, OutputIterator result, Predicate pred, const T& new_value);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Predicate, class T>
ForwardIterator2
replace_copy_if(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, Predicate pred, const T& new_value);
```

```cpp
template<input_iterator I, sentinel_for<I> S, class T1, class T2, output_iterator<const T2&> O, class Proj = identity>
requires indirectly_copyable<I, O> &&
indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T1*>;
constexpr ranges::replace_copy_result<I, O>
ranges::replace_copy(I first, S last, O result, const T1& old_value, const T2& new_value, Proj proj = {});
```

```cpp
template<input_range R, class T1, class T2, output_iterator<const T2&> O, class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*>;
constexpr ranges::replace_copy_result<borrowed_iterator_t<R>, O>
ranges::replace_copy(R&& r, O result, const T1& old_value, const T2& new_value, Proj proj = {});
```

```cpp
template<input_iterator I, sentinel_for<I> S, class T, output_iterator<const T&> O, class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>;
constexpr ranges::replace_copy_if_result<I, O>
ranges::replace_copy_if(I first, S last, O result, Pred pred, const T& new_value, Proj proj = {});
```

```cpp
template<input_range R, class T, output_iterator<const T&> O, class Proj = identity, indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>;
constexpr ranges::replace_copy_if_result<borrowed_iterator_t<R>, O>
ranges::replace_copy_if(R&& r, O result, Pred pred, const T& new_value, Proj proj = {});
```

Let E be

\[ \text{bool}((\text{first} + (i - \text{result})) == \text{old_value}) \] for replace_copy;

\[ \text{bool}(\text{pred}((\text{first} + (i - \text{result}))) \] for replace_copy_if;
— bool(invoke(proj, *(first + (i - result))) == old_value) for ranges::replace_copy;
— bool(invoke(pred, invoke(proj, *(first + (i - result)))) for ranges::replace_copy_if.

**Mandates:** The results of the expressions *first and new_value are writable (25.3.1) to result.

**Preconditions:** The ranges [first, last) and [result, result + (last - first)) do not overlap.

**Effects:** Assigns through every iterator i in the range [result, result + (last - first)) a new corresponding value

— new_value if E is true or
— *(first + (i - result)) otherwise.

**Returns:**

— result + (last - first) for the overloads in namespace std.
— {last, result + (last - first)} for the overloads in namespace ranges.

**Complexity:** Exactly last - first applications of the corresponding predicate and any projection.

### 27.7.6 Fill

[alg.fill]

```
template<class ForwardIterator, class T>
constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class T>
void fill(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, const T& value);
```

```
template<class OutputIterator, class Size, class T>
constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);
template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator fill_n(ExecutionPolicy&& exec,
                        ForwardIterator first, Size n, const T& value);
```

```
template<class T, output_iterator<const T&> O, sentinel_for<O> S>
constexpr O ranges::fill(O first, S last, const T& value);
template<class T, output_range<const T&> R>
constexpr borrowed_iterator_t<R> ranges::fill(R&& r, const T& value);
template<class T, output_iterator<const T&> O>
constexpr O ranges::fill_n(O first, iter_difference_t<O> n, const T& value);
```

1. Let \( N \) be \( \max(0, n) \) for the fill_n algorithms, and last - first for the fill algorithms.

**Mandates:** The expression value is writable (25.3.1) to the output iterator. The type Size is convertible to an integral type (7.3.9, 11.4.8).

**Effects:** Assigns value through all the iterators in the range [first, first + \( N \)].

**Returns:** first + \( N \).

**Complexity:** Exactly \( N \) assignments.

### 27.7.7 Generate

[alg.generate]

```
template<class ForwardIterator, class Generator>
constexpr void generate(ForwardIterator first, ForwardIterator last, Generator gen);
template<class ExecutionPolicy, class ForwardIterator, class Generator>
void generate(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last, Generator gen);
```

```
template<class OutputIterator, class Size, class Generator>
OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>
ForwardIterator generate_n(ExecutionPolicy&& exec,
                           ForwardIterator first, Size n, Generator gen);
```

§ 27.7.7
Let \( N \) be \( \max(0, n) \) for the \texttt{generate\_n} algorithms, and \( \text{last} - \text{first} \) for the \texttt{generate} algorithms.

\textbf{Mandates:} Size is convertible to an integral type (7.3.9, 11.4.8).

\textbf{Effects:} Assigns the result of successive evaluations of \texttt{gen()} through each iterator in the range \([\text{first}, \text{first} + N)\).

\textbf{Returns:} \text{first} + \( N \).

\textbf{Complexity:} Exactly \( N \) evaluations of \texttt{gen()} and assignments.

### 27.7.8 Remove

```
template<input_or_output_iterator O, sentinel_for<O> S, copy_constructible F>
requires invocable<F&> && indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate(O first, S last, F gen);  

template<class R, copy_constructible F>
requires invocable<F&> && output_range<R, invoke_result_t<F&>>
constexpr borrowed_iterator_t<R> ranges::generate(R&& r, F gen);  

template<input_or_output_iterator O, copy_constructible F>
requires invocable<F&> && indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate_n(O first, iter_difference_t<O> n, F gen);  
```

Let \( E \) be
\begin{enumerate}
  \item \( \text{bool(*i == value)} \) for \texttt{remove};
  \item \( \text{bool(pred(*i))} \) for \texttt{remove\_if};
  \item \( \text{bool(invoke(proj, *i) == value)} \) for \texttt{ranges::remove};
  \item \( \text{bool(invoke(pred, invoke(proj, *i)))} \) for \texttt{ranges::remove\_if}.
\end{enumerate}

\textbf{Preconditions:} For the algorithms in namespace \texttt{std}, the type of \texttt{*first} meets the \texttt{Cpp17MoveAssignabe} requirements (Table 33).
Effects: Eliminates all the elements referred to by iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) holds.

Returns: Let \( j \) be the end of the resulting range. Returns:

- \( j \) for the overloads in namespace std.
- \( \{j, \text{last}\} \) for the overloads in namespace ranges.

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

[Note 1: Each element in the range \([\text{ret}, \text{last})\), where \( \text{ret} \) is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. — end note]

```cpp
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
remove_copy(InputIterator first, InputIterator last,
OutputIterator result, const T& value);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class T>
ForwardIterator2
remove_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, const T& value);
```

```cpp
template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
remove_copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2
remove_copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);
```

```cpp
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class T,
class Proj = identity>
requires indirectly_copyable<I, O> &&
indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>
constexpr ranges::remove_copy_result<I, O>
ranges::remove_copy(I first, S last, O result, const T& value, Proj proj = {});
```

```cpp
template<input_range R, weakly_incrementable O, class T, class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>
constexpr ranges::remove_copy_result<borrowed_iterator_t<R>, O>
ranges::remove_copy(R&& r, O result, const T& value, Proj proj = {});
```

```cpp
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class T,
class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::remove_copy_if_result<I, O>
ranges::remove_copy_if(I first, S last, O result, Pred pred, Proj proj = {});
```

```cpp
template<input_range R, weakly_incrementable O, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::remove_copy_if_result<borrowed_iterator_t<R>, O>
ranges::remove_copy_if(R&& r, O result, Pred pred, Proj proj = {});
```

Let \( E \) be

- \( \text{bool(*i == value)} \) for \text{remove_copy};
- \( \text{bool(pred(*i))} \) for \text{remove_copy_if};
- \( \text{bool:invoke(proj, *i) == value)} \) for \text{ranges::remove_copy};
- \( \text{bool:invoke(pred, invoke(proj, *i)))} \) for \text{ranges::remove_copy_if}.
Let \( N \) be the number of elements in \([\text{first}, \text{last})\) for which \( E \) is false.

**Mandates:** *first* is writable (25.3.1) to \( \text{result} \).

**Preconditions:** The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) do not overlap.

[Note 2: For the overloads with an ExecutionPolicy, there might be a performance cost if \text{iterator_traits<ForwardIterator>::value_type} does not meet the \text{Cpp17MoveConstructible} (Table 31) requirements. —end note]

**Effects:** Copies all the elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) is false.

**Returns:**

1. \( \text{result} + N \), for the algorithms in namespace *std*.
2. \( \{\text{last}, \text{result} + N\} \), for the algorithms in namespace *ranges*.

**Complexity:** Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

**Remarks:** Stable (16.4.6.8).

### 27.7.9 Unique

[alg.unique]

```cpp
template<class ForwardIterator>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator unique(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                                 BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last,
                          BinaryPredicate pred);

template<permutable I, sentinel_for<I> S, class Proj = identity,
          indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
constexpr subrange<I> ranges::unique(I first, S last, C comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
          indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::unique(R&& r, C comp = {}, Proj proj = {});
```

1. Let \( \text{pred} \) be \text{equal_to}() for the overloads with no parameter \( \text{pred} \), and let \( E \) be
   1. \( \text{bool}((\text{pred}(*i - 1), *i)) \) for the overloads in namespace *std*;
   2. \( \text{bool}(\text{invoke(\text{comp}, \text{invoke(\text{proj}, *(i - 1)), \text{invoke(\text{proj}, *i)}))}) \) for the overloads in namespace *ranges*.

2. **Preconditions:** For the overloads in namespace *std*, \( \text{pred} \) is an equivalence relation and the type of *first* meets the \text{Cpp17MoveAssignable} requirements (Table 33).

3. **Effects:** For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator \( i \) in the range \([\text{first} + 1, \text{last})\) for which \( E \) is true.

4. **Returns:** Let \( j \) be the end of the resulting range. Returns:
   1. \( j \) for the overloads in namespace *std*.
   2. \( \{j, \text{last}\} \) for the overloads in namespace *ranges*.

5. **Complexity:** For nonempty ranges, exactly \( \text{(last} - \text{first}) - 1 \) applications of the corresponding predicate and no more than twice as many applications of any projection.
```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator
unique_copy(InputIterator first, InputIterator last,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
unique_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

template<class InputIterator, class OutputIterator,
class BinaryPredicate>
constexpr OutputIterator
unique_copy(InputIterator first, InputIterator last,
OutputIterator result, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator2
unique_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, BinaryPredicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Proj = identity,
indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
requires indirectly_copyable<I, O> &&
(forward_iterator<I> ||
(foreward_iterator<I> ||
(indirectly_copyable_storable<I, O>)) ||
indirectly_copyable_storable<I, O>))
constexpr ranges::unique_copy_result<I, O>
ranges::unique_copy(I first, S last, O result, C comp = {}, Proj proj = {});

template<input_range R, weakly_incrementable O, class Proj = identity,
indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires indirectly_copyable<iterator_t<R>, O> &&
(forward_iterator<iterator_t<R>> ||
(foreward_iterator<iterator_t<R>> ||
(indirectly_copyable_storable<iterator_t<R>, O>)) ||
indirectly_copyable_storable<iterator_t<R>, O>))
constexpr ranges::unique_copy_result<borrowed_iterator_t<R>, O>
ranges::unique_copy(R&& r, O result, C comp = {}, Proj proj = {});

Let `pred` be `equal_to{}` for the overloads in namespace `std` with no parameter `pred`, and let `E` be

- `bool(pred(*i, *(i - 1)))` for the overloads in namespace `std`;
- `bool(invoke(comp, invoke(proj, *i), invoke(proj, *(i - 1))))` for the overloads in
  namespace `ranges`.

**Mandates:** `*first` is writable (25.3.1) to `result`.

**Preconditions:**

- The ranges `[first, last)` and `[result, result+(last-first))` do not overlap.
- For the overloads in namespace `std`:
  - The comparison function is an equivalence relation.
  - For the overloads with no `ExecutionPolicy`, let `T` be the value type of `InputIterator`. If
    `InputIterator` models `forward_iterator` (25.3.4.11), then there are no additional
    requirements for `T`. Otherwise, if `InputIterator` meets the `Cpp17ForwardIterator`
    requirements and its value type is the same as `T`, then `T` meets the `Cpp17CopyAssignable`
    (Table 34) requirements. Otherwise, `T` meets both the `Cpp17CopyConstructible`
    (Table 32) and `Cpp17CopyAssignable` requirements. [Note 1: For the overloads with an
    `ExecutionPolicy`, there might be a performance cost if the value type of `ForwardIterator`
    does not meet both the `Cpp17CopyConstructible` and `Cpp17CopyAssignable`
    requirements. — end note]

**Effects:** Copies only the first element from every consecutive group of equal elements referred to by
the iterator `i` in the range `[first, last)` for which `E` holds.
Returns:

- \( \text{result} + N \) for the overloads in namespace `std`.
- \( \{\text{last}, \text{result} + N\} \) for the overloads in namespace `ranges`.

Complexity: Exactly \( \text{last} - \text{first} - 1 \) applications of the corresponding predicate and no more than twice as many applications of any projection.

### 27.7.10 Reverse

```cpp
template<class BidirectionalIterator>
constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last);
```

```
template<bidirectional_iterator I, sentinel_for<I> S>
requires permutable<I>
constexpr I ranges::reverse(I first, S last);

template<bidirectional_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_iterator_t<R> ranges::reverse(R&& r);
```

1. **Preconditions**: For the overloads in namespace `std`, `BidirectionalIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3).
2. **Effects**: For each non-negative integer \( i < (\text{last} - \text{first}) / 2 \), applies `std::iter_swap`, or `ranges::iter_swap` for the overloads in namespace `ranges`, to all pairs of iterators \( \text{first} + i, (\text{last} - i) - 1 \).
3. **Returns**: `last` for the overloads in namespace `ranges`.
4. **Complexity**: Exactly \( (\text{last} - \text{first})/2 \) swaps.

```cpp
template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
                                       OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator reverse_copy(ExecutionPolicy&& exec,
                             BidirectionalIterator first, BidirectionalIterator last,
                             ForwardIterator result);
```

```
template<bidirectional_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::reverse_copy_result<I, O>
ranges::reverse_copy(I first, S last, O result);

template<bidirectional_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::reverse_copy_result<borrowed_iterator_t<R>, O>
ranges::reverse_copy(R&& r, O result);
```

5. Let \( N \) be \( \text{last} - \text{first} \).
6. **Preconditions**: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + N)\) do not overlap.
7. **Effects**: Copies the range \([\text{first}, \text{last})\) to the range \([\text{result}, \text{result} + N)\) such that for every non-negative integer \( i < N \) the following assignment takes place: \( *(\text{result} + N - 1 - i) = *(\text{first} + i) \).
8. **Returns**: 
   - \( \text{result} + N \) for the overloads in namespace `std`.
   - \( \{\text{last}, \text{result} + N\} \) for the overloads in namespace `ranges`.
9. **Complexity**: Exactly \( N \) assignments.
27.7.11 Rotate

[alg.rotate]

```
template<class ForwardIterator>
constexpr ForwardIterator
class rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
class rotate(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I>
class ranges::rotate(I first, I middle, S last);
```

1. **Preconditions**: 
   - [first, middle) and [middle, last) are valid ranges. 
   - For the overloads in namespace std, ForwardIterator meets the Cpp17ValueSwappable requirements (16.4.4.3), and the type of *first meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

2. **Effects**: For each non-negative integer \( i < (last - first) \), places the element from the position \( first + i \) into position \( first + (i + (last - middle)) \% (last - first) \).
   - [Note 1: This is a left rotate. — end note]

3. **Returns**: 
   - \( first + (last - middle) \) for the overloads in namespace std.
   - \{first + (last - middle), last\} for the overload in namespace ranges.

4. **Complexity**: At most \( last - first \) swaps.

```
template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
class ranges::rotate(R&& r, iterator_t<R> middle);
```

5. **Effects**: Equivalent to: 
   - return ranges::rotate(ranges::begin(r), middle, ranges::end(r));

```
template<class ForwardIterator, class OutputIterator>
constexpr OutputIterator
rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last,
    OutputIterator result);
```

6. **Preconditions**: 
   - [first, middle) and [middle, last) are valid ranges. 
   - The ranges [first, last) and [result, result + N) do not overlap.

7. **Effects**: Copies the range [first, last) to the range [result, result + N) such that for each non-negative integer \( i < N \) the following assignment takes place: \*result + i = *(first + (i + (middle - first)) \% N).

8. **Returns**: 
   - \( result + N \) for the overloads in namespace std.
   - \{last, result + N\} for the overload in namespace ranges.

9. **Complexity**: Exactly \( N \) assignments.

```
template<forward_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::rotate_copy_result<I, O>
class ranges::rotate_copy(I first, I middle, S last, O result);
```

6. **Let \( N \) be last - first.**

7. **Preconditions**: 
   - [first, middle) and [middle, last) are valid ranges. 
   - The ranges [first, last) and [result, result + N) do not overlap.

8. **Effects**: Copies the range [first, last) to the range [result, result + N) such that for each non-negative integer \( i < N \) the following assignment takes place: \*result + i = *(first + (i + (middle - first)) \% N).

9. **Returns**: 
   - \( result + N \) for the overloads in namespace std.
   - \{last, result + N\} for the overload in namespace ranges.

10. **Complexity**: Exactly \( N \) assignments.
ranges::rotate_copy(R&& r, iterator_t<R> middle, O result);

Effects: Equivalent to:

return ranges::rotate_copy(ranges::begin(r), middle, ranges::end(r), std::move(result));

27.7.12 Sample  [alg.random.sample]

template<class PopulationIterator, class SampleIterator,
class Distance, class UniformRandomBitGenerator>
SampleIterator sample(PopulationIterator first, PopulationIterator last,
SampleIterator out, Distance n,
UniformRandomBitGenerator&& g);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Gen>
requires (forward_iterator<I> || random_access_iterator<O>) &&
indirectly_copyable<I, O> &&
uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(I first, S last, O out, iter_difference_t<I> n, Gen&& g);

template<input_range R, weakly_incrementable O, class Gen>
requires (forward_range<R> || random_access_iterator<O>) &&
indirectly_copyable<iterator_t<R>, O> &&
uniform_random_bit_generator<remove_reference_t<Gen>>
O ranges::sample(R&& r, O out, range_difference_t<R> n, Gen&& g);

1 Mandates: For the overload in namespace std, Distance is an integer type and *first is writable (25.3.1) to out.
2 Preconditions: out is not in the range [first, last). For the overload in namespace std:
(2.1) — PopulationIterator meets the Cpp17InputIterator requirements (25.3.5.3).
(2.2) — SampleIterator meets the Cpp17OutputIterator requirements (25.3.5.4).
(2.3) — SampleIterator meets the Cpp17RandomAccessIterator requirements (25.3.5.7) unless PopulationIterator models forward_iterator (25.3.4.11).
(2.4) — remove_reference_t<UniformRandomBitGenerator> meets the requirements of a uniform random bit generator type (28.5.3.3).

Effects: Copies min(last - first, n) elements (the sample) from [first, last) (the population) to out such that each possible sample has equal probability of appearance.

[Note 1: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note]

Returns: The end of the resulting sample range.

Complexity: O(last - first).

Remarks:
(6.1) — For the overload in namespace std, stable if and only if PopulationIterator models forward_iterator. For the first overload in namespace ranges, stable if and only if I models forward_iterator.
(6.2) — To the extent that the implementation of this function makes use of random numbers, the object g serves as the implementation’s source of randomness.

27.7.13 Shuffle  [alg.random.shuffle]

template<class RandomAccessIterator, class UniformRandomBitGenerator>
void shuffle(RandomAccessIterator first, RandomAccessIterator last,
UniformRandomBitGenerator&& g);

template<random_access_iterator I, sentinel_for<I> S, class Gen>
requires permutable<I> &&
uniform_random_bit_generator<remove_reference_t<Gen>>
I ranges::shuffle(I first, S last, Gen&& g);
template<random_access_range R, class Gen>
requires permutable<iterator_t<R>> &&
    uniform_random_bit_generator<remove_reference_t<Gen>>
borrowed_iterator_t<R> ranges::shuffle(R&& r, Gen&& g);

Preconditions: For the overload in namespace std:
1. RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.4.4.3).
2. The type remove_reference_t<UniformRandomBitGenerator> meets the uniform random bit
generator (28.5.3.3) requirements.

Effects: Permutes the elements in the range [first, last) such that each possible permutation of those
elements has equal probability of appearance.

Returns: last for the overloads in namespace ranges.

Complexity: Exactly (last - first) - 1 swaps.

Remarks: To the extent that the implementation of this function makes use of random numbers, the
object referenced by g shall serve as the implementation’s source of randomness.

27.7.14 Shift [alg.shift]

template<class ForwardIterator>
constexpr ForwardIterator
shift_left(ForwardIterator first, ForwardIterator last,
        typename iterator_traits<ForwardIterator>::difference_type n);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_left(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
        typename iterator_traits<ForwardIterator>::difference_type n);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::shift_left(I first, S last, iter_difference_t<I> n);

template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::shift_left(R&& r, range_difference_t<R> n)

Preconditions: n >= 0 is true. For the overloads in namespace std, the type of *first meets the
Cpp17MoveAssignable requirements.

Effects: If n == 0 or n >= last - first, does nothing. Otherwise, moves the element from position
first + n + i into position first + i for each non-negative integer i < (last - first) - n. For
the overloads without an ExecutionPolicy template parameter, does so in order starting from i = 0
and proceeding to i = (last - first) - n - 1.

Returns: Let NEW_LAST be first + (last - first - n) if n < last - first, otherwise first.

(3.1) — NEW_LAST for the overloads in namespace std.

(3.2) — {first, NEW_LAST} for the overloads in namespace ranges.

Complexity: At most (last - first) - n assignments.
constexpr borrowed_subrange_t<R> ranges::shift_right(R&& r, range_difference_t<R> n);

Preconditions: n >= 0 is true. For the overloads in namespace std, the type of \*first meets the Cpp17MoveAssignnable requirements, and ForwardIterator meets the Cpp17BidirectionalIterator requirements (25.3.5.6) or the Cpp17ValueSwappnable requirements.

Effects: If n == 0 or n >= last - first, does nothing. Otherwise, moves the element from position first + i into position first + n + i for each non-negative integer i < (last - first) - n. Does so in order starting from i = (last - first) - n - 1 and proceeding to i = 0 if:

- for the overload in namespace std without an ExecutionPolicy template parameter, ForwardIterator meets the Cpp17BidirectionalIterator requirements,
- for the overloads in namespace ranges, I models bidirectional_iterator.

Returns: Let NEW_FIRST be first + n if n < last - first, otherwise last.

Complexity: At most (last - first) - n assignments or swaps.

27.8 Sorting and related operations [alg.sorting]

27.8.1 General [alg.sorting.general]

The operations in 27.8 defined directly in namespace std have two versions: one that takes a function object of type Compare and one that uses an operator<.

Compare is a function object type (22.10) that meets the requirements for a template parameter named BinaryPredicate (27.2). The return value of the function call operation applied to an object of type Compare, when converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. Compare comp is used throughout for algorithms assuming an ordering relation.

For all algorithms that take Compare, there is a version that uses operator< instead. That is, comp(*i, *j) != false defaults to *i < *j != false. For algorithms other than those described in 27.8.4, comp shall induce a strict weak ordering on the values.

The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the requirements are that comp and equiv both be transitive relations:

(4.1) — comp(a, b) && comp(b, c) implies comp(a, c)
(4.2) — equiv(a, b) && equiv(b, c) implies equiv(a, c)

[Note 1: Under these conditions, it can be shown that]

(4.3) — equiv is an equivalence relation,
(4.4) — comp induces a well-defined relation on the equivalence classes determined by equiv, and
(4.5) — the induced relation is a strict total ordering.

— end note]

A sequence is sorted with respect to a comp and proj for a comparator and projection comp and proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence,

bool invoke(comp, invoke(proj, *(i + n)), invoke(proj, *i))

is false.

A sequence is sorted with respect to a comparator comp for a comparator comp if it is sorted with respect to comp and identity{} (the identity projection).

A sequence [start, finish) is partitioned with respect to an expression f(a) if there exists an integer n such that for all 0 <= i < (finish - start), f(*(start + i)) is true if and only if i < n.

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an operator==, but an equivalence relation induced by the strict weak ordering. That is, two elements a and b are considered equivalent if and only if !(a < b) && !(b < a).
27.8.2 Sorting

27.8.2.1 sort

```cpp
template<class RandomAccessIterator>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last,
                    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last,
          Compare comp);
```

```cpp
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I ranges::sort(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R> ranges::sort(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17Value-Swappable` requirements (16.4.4.3) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 31) and `Cpp17MoveAssignable` (Table 33) requirements.

Effects: Sorts the elements in the range `[first, last)` with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Let `N` be `last - first`. $O(N \log N)$ comparisons and projections.

27.8.2.2 stable_sort

```cpp
template<class RandomAccessIterator>
constexpr void stable_sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
                           Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void stable_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
```

```cpp
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I ranges::stable_sort(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R> ranges::stable_sort(R&& r, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.
Preconditions: For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 31) and `Cpp17MoveAssignable` (Table 33) requirements.

Effects: Sorts the elements in the range `[first, last)` with respect to `comp` and `proj`.

Returns: `last` for the overloads in namespace `ranges`.

Complexity: Let \( N \) be `last - first`. If enough extra memory is available, \( N \log(N) \) comparisons. Otherwise, at most \( N \log^2(N) \) comparisons. In either case, twice as many projections as the number of comparisons.

Remarks: Stable (16.4.6.8).

### 27.8.2.3 `partial_sort`

```cpp
template<class RandomAccessIterator>
constexpr void partial_sort(RandomAccessIterator first,
                            RandomAccessIterator middle,
                            RandomAccessIterator last);
```

```cpp
template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void partial_sort(RandomAccessIterator first,
                            RandomAccessIterator middle,
                            RandomAccessIterator last,
                            Compare comp);
```

```cpp
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last,
                 Compare comp);
```

```cpp
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
partial_sort(I first, I middle, S last, Comp comp = {}, Proj proj = {});
```

1. Let `comp` be `less()` and `proj` be `identity()` for the overloads with no parameters by those names.

2. Preconditions: `[first, middle)` and `[middle, last)` are valid ranges. For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 31) and `Cpp17MoveAssignable` (Table 33) requirements.

3. Effects: Places the first `middle - first` elements from the range `[first, last)` as sorted with respect to `comp` and `proj` into the range `[first, middle)`. The rest of the elements in the range `[middle, last)` are placed in an unspecified order.

4. Returns: `last` for the overload in namespace `ranges`.

5. Complexity: Approximately \( (last - first) \times \log(middle - first) \) comparisons, and twice as many projections.

```cpp
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
partial_sort(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});
```

6. Effects: Equivalent to:

   ```cpp
   return ranges::partial_sort(ranges::begin(r), middle, ranges::end(r), comp, proj);
   ```

§ 27.8.2.3
27.8.2.4 partial_sort_copy

```
template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
                  RandomAccessIterator result_first,
                  RandomAccessIterator result_last);
```

```
template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
                 ForwardIterator first, ForwardIterator last,
                 RandomAccessIterator result_first,
                 RandomAccessIterator result_last);
```

```
template<class InputIterator, class RandomAccessIterator,
         class Compare>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
                  RandomAccessIterator result_first,
                  RandomAccessIterator result_last,
                  Compare comp);
```

```
template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator,
         class Compare>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
                 ForwardIterator first, ForwardIterator last,
                 RandomAccessIterator result_first,
                 RandomAccessIterator result_last,
                 Compare comp);
```

```
template<input_iterator I1, sentinel_for<I1> S1, random_access_iterator I2, sentinel_for<I2> S2,
           class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<I1, I2> && sortable<I2, Comp, Proj2> &&
indirect_strict_weak_order<Comp, projected<I1, Proj1>, projected<I2, Proj2>>
constexpr ranges::partial_sort_copy_result<I1, I2>
ranges::partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last,
                          Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

```
template<input_range R1, random_access_range R2, class Comp = ranges::less,
           class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<iterator_t<R1>, iterator_t<R2>> &&
indirect_strict_weak_order<Comp, projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>>
constexpr ranges::partial_sort_copy_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::partial_sort_copy(R1&& r, R2&& result_r, Comp comp = {},
                         Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let \( N \) be \( \min(last - first, result_last - result_first) \). Let \( \text{comp} \) be \text{less}(), and \( \text{proj1} \) and \( \text{proj2} \) be \text{identity}() for the overloads with no parameters by those names.

**Mandates:** For the overloads in namespace \text{std}, the expression \(*\text{first} \) is writable (25.3.1) to \text{result}_-\text{first}. Let \( \text{comp} \) be \text{less}(), and \( \text{proj1} \) and \( \text{proj2} \) be \text{identity}() for the overloads with no parameters by those names.

**Preconditions:** For the overloads in namespace \text{std}, \text{RandomAccessIterator} meets the \text{Cpp17Value-Swappable} requirements (16.4.4.3), the type of \(*\text{result}_\text{first} \) meets the \text{Cpp17MoveConstructible} (Table 31) and \text{Cpp17MoveAssignable} (Table 33) requirements.

For iterators \( a1 \) and \( b1 \) in \([\text{first}, \text{last})\), and iterators \( x2 \) and \( y2 \) in \([\text{result}_\text{first}, \text{result}_\text{last})\), after evaluating the assignment \(*y2 = *b1 \), let \( E \) be the value of

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj1}, \*a1), \text{invoke}(\text{proj2}, \*y2)))).
\]

Then, after evaluating the assignment \(*x2 = *a1, \) \( E \) is equal to

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj2}, \*x2), \text{invoke}(\text{proj2}, \*y2))).
\]

[Note 1: Writing a value from the input range into the output range does not affect how it is ordered by \text{comp} and \text{proj1} or \text{proj2}. — end note]
Effects: Places the first \( N \) elements as sorted with respect to \( \text{comp} \) and \( \text{proj2} \) into the range \([\text{result} - \text{first}, \text{result} - \text{first} + \text{N})\).

Returns:

(6.1) \( \text{result} - \text{first} + \text{N} \) for the overloads in namespace \( \text{std} \).

(6.2) \{\text{last, result}_-\text{first} + \text{N} \} for the overloads in namespace \( \text{ranges} \).

Complexity: Approximately \((\text{last} - \text{first}) \times \log \text{N}\) comparisons, and twice as many projections.

### 27.8.2.5 \( \text{is_sorted} \)[is.sorted]

```cpp
template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);
```

**Effects:** Equivalent to: \( \text{return is_sorted_until(first, last)} == \text{last} \);

```cpp
template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec, 
ForwardIterator first, ForwardIterator last);
```

**Effects:** Equivalent to: \( \text{return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last)} == \text{last} \);

```cpp
template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last, 
Compare comp);
```

**Effects:** Equivalent to: \( \text{return is_sorted_until(first, last, comp)} == \text{last} \);

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec, 
ForwardIterator first, ForwardIterator last, 
Compare comp);
```

**Effects:** Equivalent to: \( \text{return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp)} == \text{last} \);

```cpp
template<forward_iterator I, sentinel_for<I> S, class Proj = identity, 
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_sorted(I first, S last, Comp comp = {}, Proj proj = {});
```

**Effects:** Equivalent to: \( \text{return ranges::is_sorted_until(first, last, comp, proj)} == \text{last} \);
template<forward_range R, class Proj = identity, indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::is_sorted_until(R&& r, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Returns: The last iterator \( i \) in [first, last] for which the range \([\text{first}, i)\) is sorted with respect to comp and proj.

Complexity: Linear.

27.8.3 Nth element

template<class RandomAccessIterator>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator nth, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth, RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator nth, RandomAccessIterator last, Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::nth_element(I first, I nth, S last, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Preconditions: [first, nth) and [nth, last) are valid ranges. For the overloads in namespace std, RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.4.4.3), and the type of *first meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

Effects: After nth_element the element in the position pointed to by \( nth \) is the element that would be in that position if the whole range were sorted with respect to comp and proj, unless nth == last. Also for every iterator \( i \) in the range [first, nth) and every iterator \( j \) in the range [nth, last) it holds that: bool(invoke(comp, invoke(proj, *j), invoke(proj, *i))) is false.

Returns: last for the overload in namespace ranges.

Complexity: For the overloads with no ExecutionPolicy, linear on average. For the overloads with an ExecutionPolicy, \( O(N) \) applications of the predicate, and \( O(N \log N) \) swaps, where \( N = \text{last} - \text{first} \).

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::nth_element(R&& r, iterator_t<R> nth, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:

\[
\text{return ranges::nth_element(ranges::begin(r), nth, ranges::end(r), comp, proj)};
\]

27.8.4 Binary search

27.8.4.1 General

All of the algorithms in 27.8.4 are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be
logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

27.8.4.2 lower_bound

```
template<class ForwardIterator, class T>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last,
const T& value);
```

```
template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last,
const T& value, Compare comp);
```

```
template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::lower_bound(I first, S last, const T& value, Comp comp = {},
Proj proj = {});
```

```
template<forward_range R, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
ranges::less>
constexpr borrowed_iterator_t<R>
ranges::lower_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});
```

Let \( \text{comp} \) be \( \text{less}{} \) and \( \text{proj} \) be \( \text{identity}{} \) for overloads with no parameters by those names.

1. **Preconditions**: The elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expression

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, e), \text{value})).
\]

2. **Returns**: The furthermost iterator \( i \) in the range \([\text{first}, \text{last})\) such that for every iterator \( j \) in the range \([\text{first}, i)\), \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *j), \text{value})) \) is true.

3. **Complexity**: At most \( \log_2(\text{last} - \text{first}) + \theta(1) \) comparisons and projections.

27.8.4.3 upper_bound

```
template<class ForwardIterator, class T>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last,
const T& value);
```

```
template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last,
const T& value, Compare comp);
```

```
template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::upper_bound(I first, S last, const T& value, Comp comp = {},
Proj proj = {});
```

```
template<forward_range R, class T, class Proj = identity,
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp =
ranges::less>
constexpr borrowed_iterator_t<R>
ranges::upper_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});
```

Let \( \text{comp} \) be \( \text{less}{} \) and \( \text{proj} \) be \( \text{identity}{} \) for overloads with no parameters by those names.

1. **Preconditions**: The elements \( e \) of \([\text{first}, \text{last})\) are partitioned with respect to the expression

\[
\neg\text{bool}(\text{invoke}(\text{comp}, \text{value}, \text{invoke}(\text{proj}, e))).
\]

2. **Returns**: The furthermost iterator \( i \) in the range \([\text{first}, \text{last})\) such that for every iterator \( j \) in the range \([\text{first}, i)\), \( \neg\text{bool}(\text{invoke}(\text{comp}, \text{value}, \text{invoke}(\text{proj}, *j))) \) is true.

3. **Complexity**: At most \( \log_2(\text{last} - \text{first}) + \theta(1) \) comparisons and projections.
27.8.4.4 \textit{equal\_range} [\textit{equal\_range}]

\begin{verbatim}
template<class ForwardIterator, class T>
constexpr pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                   ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
    equal_range(ForwardIterator first,
                   ForwardIterator last, const T& value,
                   Compare comp);
\end{verbatim}

\begin{verbatim}
template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr subrange<I> ranges::equal_range(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_subrange_t<R> ranges::equal_range(R&& r, const T& value, Comp comp = {}, Proj proj = {});
\end{verbatim}

1 Let \textit{comp} be \texttt{less{}} and \textit{proj} be \texttt{identity{}} for overloads with no parameters by those names.

2 \textit{ Preconditions:} The elements \texttt{e} of \texttt{[first, last)} are partitioned with respect to the expressions 
\texttt{bool(invoke(comp, invoke(proj, e), value))} and \texttt{!bool(invoke(comp, value, invoke(proj, e)))}. Also, for all elements \texttt{e} of \texttt{[first, last)}, \texttt{bool(comp(e, value))} implies \texttt{!bool(comp(value, e))} for the overloads in \textit{namespace std}.

3 \textit{ Returns:}

\begin{enumerate}
\item For the overloads in \textit{namespace std}:
\begin{verbatim}
{lower_bound(first, last, value, comp),
 upper_bound(first, last, value, comp)}
\end{verbatim}
\item For the overloads in \textit{namespace ranges}:
\begin{verbatim}
{ranges::lower_bound(first, last, value, comp, proj),
 ranges::upper_bound(first, last, value, comp, proj)}
\end{verbatim}
\end{enumerate}

4 \textit{Complexity:} At most \texttt{2 \ast \log_2(last - first) + \Theta(1)} comparisons and projections.

27.8.4.5 \textit{binary\_search} [\textit{binary\_search}]

\begin{verbatim}
template<class ForwardIterator, class T>
constexpr bool
    binary_search(ForwardIterator first, ForwardIterator last,
                  const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr bool
    binary_search(ForwardIterator first, ForwardIterator last,
                  const T& value, Compare comp);
\end{verbatim}

\begin{verbatim}
template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(I first, S last, const T& value, Comp comp = {},
                                      Proj proj = {});

template<forward_range R, class T, class Proj = identity,
        indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(R&& r, const T& value, Comp comp = {},
                                      Proj proj = {});
\end{verbatim}

1 Let \textit{comp} be \texttt{less{}} and \textit{proj} be \texttt{identity{}} for overloads with no parameters by those names.

2 \textit{ Preconditions:} The elements \texttt{e} of \texttt{[first, last)} are partitioned with respect to the expressions 
\texttt{bool(invoke(comp, invoke(proj, e), value))} and \texttt{!bool(invoke(comp, value, invoke(proj, e)))}. Also, for all elements \texttt{e} of \texttt{[first, last)}, \texttt{bool(comp(e, value))} implies \texttt{!bool(comp(value, e))} for the overloads in \textit{namespace std}.

\section*{§ 27.8.4.5}
Also, for all elements $e$ of $[\text{first, last})$, bool(comp($e$, value)) implies !bool(comp(value, $e$)) for the overloads in namespace std.

Returns: true if and only if for some iterator $i$ in the range $[\text{first, last})$, !bool(invoke(comp, invoke(proj, $i$), value)) & & !bool(invoke(comp, value, invoke(proj, $i$))) is true.

Complexity: At most $\log_2(\text{last} - \text{first}) + \Theta(1)$ comparisons and projections.

27.8.5 Partitions

[alg.partitions]

template<class InputIterator, class Predicate>
constexpr bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool is_partitioned(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
 indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::is_partitioned(I first, S last, Pred pred, Proj proj = {});

template<input_range R, class Proj = identity,
 indirect_unary_predicate<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::is_partitioned(R&& r, Pred pred, Proj proj = {});

1 Let $proj$ be identity{} for the overloads with no parameter named $proj$.

Returns: true if and only if the elements $e$ of $[\text{first, last})$ are partitioned with respect to the expression bool(invoke(pred, invoke(proj, e))).

Complexity: Linear. At most last - first applications of pred and proj.

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator partition(ForwardIterator first, ForwardIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator partition(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

template<permutable I, sentinel_for<I> S, class Proj = identity,
 indirect_unary_predicate<projected<iterator_t<I>, Proj>> Pred>
constexpr subrange<I> ranges::partition(I first, S last, Pred pred, Proj proj = {});

template<forward_range R, class Proj = identity,
 indirect_unary_predicate<iterator_t<R>, Proj>> Pred>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::partition(R&& r, Pred pred, Proj proj = {});

1 Let $proj$ be identity{} for the overloads with no parameter named $proj$ and let $E(x)$ be bool(invoke(pred, invoke(proj, $x$))).

2 Preconditions: For the overloads in namespace std, ForwardIterator meets the Cpp17ValueSwappable requirements (16.4.4.3).

3 Effects: Places all the elements $e$ in $[\text{first, last})$ that satisfy $E(e)$ before all the elements that do not.

4 Returns: Let $i$ be an iterator such that $E(*j)$ is true for every iterator $j$ in $[\text{first, i})$ and false for every iterator $j$ in $[i, \text{last})$. Returns:

5 — $i$ for the overloads in namespace std.

6 — $\{i, \text{last}\}$ for the overloads in namespace ranges.

7 Complexity: Let $N = \text{last} - \text{first}$:

8 — For the overload with no ExecutionPolicy, exactly $N$ applications of the predicate and projection. At most $N/2$ swaps if the type of first meets the Cpp17BidirectionalIterator requirements for the overloads in namespace std or models bidirectional_iterator for the overloads in namespace ranges, and at most $N$ swaps otherwise.
For the overload with an ExecutionPolicy, $\mathcal{O}(N \log N)$ swaps and $\mathcal{O}(N)$ applications of the predicate.

```cpp
template<class BidirectionalIterator, class Predicate>
BidirectionalIterator
constexpr stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

template<class ExecutionPolicy, class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(ExecutionPolicy&& exec, 
BidirectionalIterator first, BidirectionalIterator last, Predicate pred);
```

Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let $E(x)$ be `bool(invoke(pred, invoke(proj, x)))`.

Preconditions: For the overloads in namespace `std`, `BidirectionalIterator` meets the Cpp17Value-Swappable requirements (16.4.4.3) and the type of `*first` meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

Effects: Places all the elements $e$ in `[first, last)` that satisfy $E(e)$ before all the elements that do not. The relative order of the elements in both groups is preserved.

Returns: Let $i$ be an iterator such that for every iterator $j$ in `[i, last)`, $E(*j)$ is `true`, and for every iterator $j$ in the range `[i, first)`, $E(*j)$ is `false`. Returns:

- `$i$` for the overloads in namespace `std`
- `{i, last) for the overloads in namespace `ranges`.

Complexity: Let $N = last - first$:

- For the overloads with no ExecutionPolicy, at most $N \log_2 N$ swaps, but only $\mathcal{O}(N)$ swaps if there is enough extra memory. Exactly $N$ applications of the predicate and projection.
- For the overload with an ExecutionPolicy, $\mathcal{O}(N \log N)$ swaps and $\mathcal{O}(N)$ applications of the predicate.
constexpr ranges::partition_copy_result<borrowed_iterator_t<R>, O1, O2>
ranges::partition_copy(R&& r, O1 out_true, O2 out_false, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let E(x) be bool(invoke(
pred, invoke(proj, x))).

Mandates: For the overloads in namespace std, the expression *first is writable (25.3.1) to out_true
and out_false.

 Preconditions: The input range and output ranges do not overlap.

[Note 1: For the overload with an ExecutionPolicy, there might be a performance cost if first’s value type
does not meet the Cpp17CopyConstructible requirements. —end note]

Effects: For each iterator i in [first, last), copies *i to the output range beginning with out_true if
E(*i) is true, or to the output range beginning with out_false otherwise.

Returns: Let o1 be the end of the output range beginning at out_true, and o2 the end of the output
range beginning at out_false. Returns

\(\{o1, o2\}\) for the overloads in namespace std.
\(\{last, o1, o2\}\) for the overloads in namespace ranges.

Complexity: Exactly last - first applications of pred and proj.

\[27.8.6\] Merge

\[\text{alg.merge}\]

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
merge(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator
    merge(ExecutionPolicy&& exec,
        ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2,
        ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
    constexpr ranges::merge_result<I1, I2, O> ranges::merge(I1 first1, S1 last1, I2 first2, S2 last2, O result,
        Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
    constexpr ranges::merge_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O> ranges::merge(R1&& r1, R2&& r2, O result,
        Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let \( N \) be \((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})\). Let \( \text{comp} \) be \{less\}, \( \text{proj1} \) be \{identity\}, and \( \text{proj2} \) be \{identity\}, for the overloads with no parameters by those names.

Preconditions: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies all the elements of the two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into the range \([\text{result}, \text{result_last})\), where \( \text{result} + N \) is \( \text{result_last} \). If an element \( a \) precedes \( b \) in an input range, \( a \) is copied into the output range before \( b \). If \( e1 \) is an element of \([\text{first1}, \text{last1})\) and \( e2 \) of \([\text{first2}, \text{last2})\), \( e2 \) is copied into the output range before \( e1 \) if and only if \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj2}, e2), \text{invoke}(\text{proj1}, e1))) \) is true.

Returns:
1. \( \text{result_last} \) for the overloads in namespace \text{std}.
2. \( \{\text{last1}, \text{last2}, \text{result_last}\} \) for the overloads in namespace \text{ranges}.

Complexity:
1. For the overloads with no \text{ExecutionPolicy}, at most \( N - 1 \) comparisons and applications of each projection.
2. For the overloads with an \text{ExecutionPolicy}, \( O(N) \) comparisons.

Remarks: Stable (16.4.6.8).
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity> 
requires sortable<I, Comp, Proj> 
constexpr I ranges::inplace_merge(I first, I middle, S last, Comp comp = {}, Proj proj = {});

Let \textit{comp} be \textit{less}{} and \textit{proj} be \textit{identity}{} for the overloads with no parameters by those names.

Preconditions: \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) are valid ranges sorted with respect to \textit{comp} and \textit{proj}. For the overloads in namespace \textit{std}, \textit{BidirectionalIterator} meets the \textit{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of \*\textit{first} meets the \textit{Cpp17MoveConstructible} (Table 31) and \textit{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Merges two sorted consecutive ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\), putting the result of the merge into the range \([\text{first}, \text{last})\). The resulting range is sorted with respect to \textit{comp} and \textit{proj}.

Returns: \textit{last} for the overload in namespace \textit{ranges}.

Complexity: Let \(N = \text{last} - \text{first}\):

\[\text{(11.1)}\]
- For the overloads with no \textit{ExecutionPolicy}, and if enough additional memory is available, exactly \(N - 1\) comparisons.

\[\text{(11.2)}\]
- Otherwise, \(O(N \log N)\) comparisons.

In either case, twice as many projections as comparisons.

Remarks: Stable (16.4.6.8).

template<bidirectional_range R, class Comp = ranges::less, class Proj = identity> 
requires sortable<iterator_t<R>, Comp, Proj> 
constexpr borrowed_iterator_t<R> 
ranges::inplace_merge(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:

\[\text{return ranges::inplace_merge(ranges::begin(r), middle, ranges::end(r), comp, proj);}\]

27.8.7 Set operations on sorted structures \[\textit{[alg.set.operations]}\]

27.8.7.1 General \[\textit{[alg.set.operations.general]}\]

Subclause 27.8.7 defines all the basic set operations on sorted structures. They also work with \textit{multisets} (24.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to \textit{multisets} in a standard way by defining \textit{set_union} to contain the maximum number of occurrences of every element, \textit{set_intersection} to contain the minimum, and so on.

27.8.7.2 \textit{includes} \[\textit{[includes]}\]

template<class InputIterator1, class InputIterator2> 
constexpr bool includes(InputIterator1 first1, InputIterator1 last1, 
InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2> 
bool includes(ExecutionPolicy&& exec, 
ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare> 
constexpr bool includes(InputIterator1 first1, InputIterator1 last1, 
InputIterator2 first2, InputIterator2 last2, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare> 
bool includes(ExecutionPolicy&& exec, 
ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, 
class Proj1 = identity, class Proj2 = identity, 
indirect_strict_weak_order<projected<I1, Proj1>, 
projected<I2, Proj2>> Comp = ranges::less> 
constexpr bool ranges::includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {}),
Proj1 proj1 = {}, Proj2 proj2 = {};

template<input_range R1, input_range R2, class Proj1 = identity,
class Proj2 = identity,
indirect_strict_weak_order<projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(R1&& r1, R2&& r2, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let \( \text{comp} \) be \( \text{less}{} \), \( \text{proj1} \) be \( \text{identity}{} \), and \( \text{proj2} \) be \( \text{identity}{} \), for the overloads with no parameters by those names.

2 **Preconditions:** The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively.

3 **Returns:** \( \text{true} \) if and only if \([\text{first2}, \text{last2})\) is a subsequence of \([\text{first1}, \text{last1})\).

[Note 1: A sequence \( S \) is a subsequence of another sequence \( T \) if \( S \) can be obtained from \( T \) by removing some, all, or none of \( T \)'s elements and keeping the remaining elements in the same order. — end note]

4 **Complexity:** At most \( 2 * ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1 \) comparisons and applications of each projection.

### 27.8.7.3 set_union

**[set.union]**

```c++
#include <ranges>

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_union(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator, class Compare>
ForwardIterator
set_union(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
weakly_incrementable O, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_union_result<I1, I2, O>
ranges::set_union(I1 first1, S1 last1, I2 first2, S2 last2, 0 result, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O,
class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable_iterator_t<R1>, iterator_t<R2>, 0, Comp, Proj1, Proj2>
constexpr ranges::set_union_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_union(R1&& r1, R2&& r2, 0 result, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});
```

1 Let \( \text{comp} \) be \( \text{less}{} \), and \( \text{proj1} \) and \( \text{proj2} \) be \( \text{identity}{} \) for the overloads with no parameters by those names.
Preconditions: The ranges \([\text{first}_1, \text{last}_1)\) and \([\text{first}_2, \text{last}_2)\) are sorted with respect to \text{comp} and \text{proj}_1 or \text{proj}_2, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

Returns: Let \text{result}_\text{last} be the end of the constructed range. Returns

\[
\text{result}_\text{last} \quad \text{(4.1)}
\]

for the overloads in namespace \text{std}.

\[
\{\text{last}_1, \text{last}_2, \text{result}_\text{last}\} \quad \text{(4.2)}
\]

for the overloads in namespace \text{ranges}.

Complexity: At most \(2 \ast ((\text{last}_1 - \text{first}_1) + (\text{last}_2 - \text{first}_2)) - 1\) comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If \([\text{first}_1, \text{last}_1)\) contains \(m\) elements that are equivalent to each other and \([\text{first}_2, \text{last}_2)\) contains \(n\) elements that are equivalent to them, then all \(m\) elements from the first range are copied to the output range, in order, and then the final \(\max(n - m, 0)\) elements from the second range are copied to the output range, in order.

27.8.7.4 \text{set_intersection}

\[
\text{template<class InputIterator1, class InputIterator2, class OutputIterator>}
\]

\[
\text{constexpr OutputIterator}
\]

\[
\text{set_intersection(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result);}
\]

\[
\text{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>}
\]

\[
\text{ForwardIterator}
\]

\[
\text{set_intersection(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result);}
\]

\[
\text{template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>}
\]

\[
\text{constexpr OutputIterator}
\]

\[
\text{set_intersection(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp);}
\]

\[
\text{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>}
\]

\[
\text{ForwardIterator}
\]

\[
\text{set_intersection(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result, Compare comp);}
\]

\[
\text{template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>}
\]

\[
\text{requires mergeable<I1, I2, O, Comp, Proj1, Proj2>}
\]

\[
\text{constexpr ranges::set_intersection_result<I1, I2, O>}
\]

\[
\text{ranges::set_intersection_result<\text{I1 first}_1, \text{I1 last}_1, \text{I2 first}_2, \text{I2 last}_2, 0, \text{result}, \text{Comp comp} = {}, \text{Proj1 proj}_1 = {}, \text{Proj2 proj}_2 = {}};
\]

\[
\text{template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>}
\]

\[
\text{requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>}
\]

\[
\text{constexpr ranges::set_intersection_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, 0, \text{Comp comp} = {}, \text{Proj1 proj}_1 = {}, \text{Proj2 proj}_2 = {}}}
\]

Let \text{comp} be \text{less}(), and \text{proj}_1 and \text{proj}_2 be \text{identity}() for the overloads with no parameters by those names.
Preconditions: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \text{comp} and \text{proj1} or \text{proj2}, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

Returns: Let \(\text{result_last}\) be the end of the constructed range. Returns

\[\text{(4.1)}\] \(\text{result_last}\) for the overloads in namespace \text{std}.

\[\text{(4.2)}\] \{\text{last1}, \text{last2}, \text{result_last}\} for the overloads in namespace \text{ranges}.

Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, the first \(\min(m, n)\) elements are copied from the first range to the output range, in order.

27.8.7.5 \text{set_difference} \hfill [set.difference]

\begin{verbatim}
template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
set_difference(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator
set_difference(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<I1, O>
ranges::set_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<borrowed_iterator_t<R1>, O>
ranges::set_difference(R1&& r1, R2&& r2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
\end{verbatim}

Let \text{comp} be \text{less}\{\}, and \text{proj1} and \text{proj2} be \text{identity}\{\} for the overloads with no parameters by those names.

Preconditions: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \text{comp} and \text{proj1} or \text{proj2}, respectively. The resulting range does not overlap with either of the original ranges.
**Effects:** Copies the elements of the range \([\text{first1}, \text{last1})\) which are not present in the range \([\text{first2}, \text{last2})\) to the range beginning at \(\text{result}\). The elements in the constructed range are sorted.

**Returns:** Let \(\text{result}\_\text{last}\) be the end of the constructed range. Returns

- \(\text{result}\_\text{last}\) for the overloads in namespace std.
- \(\{\text{last1}, \text{result}\_\text{last}\}\) for the overloads in namespace ranges.

**Complexity:** At most \(2 \ast ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons and applications of each projection.

**Remarks:** If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, the last \(\max(m - n, 0)\) elements from \([\text{first1}, \text{last1})\) are copied to the output range, in order.

### 27.8.7.6 set_symmetric_difference

```
template<class InputIterator1, class InputIterator2, 
         class OutputIterator>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1, 
                         InputIterator2 first2, InputIterator2 last2, 
                         OutputIterator result);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
         class ForwardIterator>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec, 
                        ForwardIterator1 first1, ForwardIterator1 last1, 
                        ForwardIterator2 first2, ForwardIterator2 last2, 
                        ForwardIterator result);
```

```
template<class InputIterator1, class InputIterator2, 
         class OutputIterator, class Compare>
constexpr OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1, 
                         InputIterator2 first2, InputIterator2 last2, 
                         OutputIterator result, Compare comp);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
         class ForwardIterator, class Compare>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec, 
                        ForwardIterator1 first1, ForwardIterator1 last1, 
                        ForwardIterator2 first2, ForwardIterator2 last2, 
                        ForwardIterator result, Compare comp);
```

```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, 
          weakly_incrementable O, class Comp = ranges::less, 
          class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<I1, I2, O>
ranges::set_symmetric_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result, 
                                Comp comp = {}, Proj1 proj1 = {}, 
                                Proj2 proj2 = {});
```

```
template<input_range R1, input_range R2, weakly_incrementable O, 
          class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<borrowed_iterator_t<R1>, 
                                                  borrowed_iterator_t<R2>, O>
ranges::set_symmetric_difference(R1&& r1, R2&& r2, O result, Comp comp = {}, 
                                Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let \(\text{comp}\) be \(\text{less}\{\}\), and \(\text{proj1}\) and \(\text{proj2}\) be \(\text{identity}\{\}\) for the overloads with no parameters by those names.

**Preconditions:** The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \(\text{comp}\) and \(\text{proj1}\) or \(\text{proj2}\), respectively. The resulting range does not overlap with either of the original ranges.
Effects: Copies the elements of the range \([\text{first}_1, \text{last}_1]\) that are not present in the range \([\text{first}_2, \text{last}_2]\), and the elements of the range \([\text{first}_2, \text{last}_2]\) that are not present in the range \([\text{first}_1, \text{last}_1]\) to the range beginning at result. The elements in the constructed range are sorted.

Returns: Let result_last be the end of the constructed range. Returns

- \((4.1)\) result_last for the overloads in namespace std.
- \((4.2)\) \(\{\text{last}_1, \text{last}_2, \text{result}_\text{last}\}\) for the overloads in namespace ranges.

Complexity: At most \(2 \times ((\text{last}_1 - \text{first}_1) + (\text{last}_2 - \text{first}_2)) - 1\) comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If \([\text{first}_1, \text{last}_1]\) contains \(m\) elements that are equivalent to each other and \([\text{first}_2, \text{last}_2]\) contains \(n\) elements that are equivalent to them, then \(|m - n|\) of those elements shall be copied to the output range: the last \(m - n\) of these elements from \([\text{first}_1, \text{last}_1]\) if \(m > n\), and the last \(n - m\) of these elements from \([\text{first}_2, \text{last}_2]\) if \(m < n\). In either case, the elements are copied in order.

27.8.8 Heap operations

27.8.8.1 General

A random access range \([a, b)\) is a heap with respect to comp and proj for a comparator and projection comp and proj if its elements are organized such that:

- \((1.1)\) With \(N = b - a\), for all \(i, 0 < i < N\), \(\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, a[\lfloor i/2 \rfloor]), \text{invoke}(\text{proj}, a[i])))\) is false.
- \((1.2)\) \(*a\) may be removed by pop_heap, or a new element added by push_heap, in \(O(\log N)\) time.

These properties make heaps useful as priority queues.

make_heap converts a range into a heap and sort_heap turns a heap into a sorted sequence.

27.8.8.2 push_heap

```cpp
template<class RandomAccessIterator>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last,
                         Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::push_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::push_heap(R&& r, Comp comp = {}, Proj proj = {});
```

Let comp be \(\text{less}\{\}\) and proj be \(\text{identity}\{\}\) for the overloads with no parameters by those names.

Preconditions: The range \([\text{first}, \text{last} - 1)\) is a valid heap with respect to \text{comp} and \text{proj}. For the overloads in namespace std, RandomAccessIterator meets the \(\text{Cpp17ValueSwappable}\) requirements (16.4.4.3) and the type of \(*\text{first}\) meets the \(\text{Cpp17MoveConstructible}\) requirements (Table 31) and the \(\text{Cpp17MoveAssignable}\) requirements (Table 33).

Effects: Places the value in the location \(\text{last} - 1\) into the resulting heap \([\text{first}, \text{last})\).

Returns: last for the overloads in namespace ranges.

Complexity: At most \(\log(\text{last} - \text{first})\) comparisons and twice as many projections.

27.8.8.3 pop_heap

```cpp
template<class RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```
template<class RandomAccessIterator, class Compare>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last, 
             Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, 
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::pop_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::pop_heap(R&& r, Comp comp = {}, Proj proj = {});

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

Preconditions: The range \([\texttt{first}, \texttt{last})\) is a valid non-empty heap with respect to \texttt{comp} and \texttt{proj}. For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \textit{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of \*\texttt{first} meets the \textit{Cpp17MoveConstructible} (Table 31) and \textit{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Swaps the value in the location \texttt{first} with the value in the location \texttt{last - 1} and makes \([\texttt{first}, \texttt{last} - 1)\) into a heap with respect to \texttt{comp} and \texttt{proj}.

Returns: \texttt{last} for the overloads in namespace \texttt{ranges}.

Complexity: At most \(2 \log(\texttt{last} - \texttt{first})\) comparisons and twice as many projections.

27.8.8.4 make_heap [make.heap]

template<class RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last, 
             Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, 
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::make_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::make_heap(R&& r, Comp comp = {}, Proj proj = {});

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \textit{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of \*\texttt{first} meets the \textit{Cpp17MoveConstructible} (Table 31) and \textit{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Constructs a heap with respect to \texttt{comp} and \texttt{proj} out of the range \([\texttt{first}, \texttt{last})\).

Returns: \texttt{last} for the overloads in namespace \texttt{ranges}.

Complexity: At most \(3(\texttt{last} - \texttt{first})\) comparisons and twice as many projections.

27.8.8.5 sort_heap [sort.heap]

template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last, 
             Compare comp);
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
    requires sortable<I, Comp, Proj>
constexpr I
    ranges::sort_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
    requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::sort_heap(R&& r, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Preconditions: The range [first, last) is a valid heap with respect to comp and proj. For the overloads
    in namespace std, RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.4.4.3)
and the type of *first meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable
    (Table 33) requirements.

Effects: Sorts elements in the heap [first, last) with respect to comp and proj.

Returns: last for the overloads in namespace ranges.

Complexity: At most 2N log N comparisons, where N = last - first, and twice as many projections.

27.8.8.6 is_heap

template<class RandomAccessIterator>
    constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
    Effects: Equivalent to: return is_heap_until(first, last) == last;

template<class ExecutionPolicy, class RandomAccessIterator>
    bool is_heap(ExecutionPolicy&& exec,
                    RandomAccessIterator first, RandomAccessIterator last);
    Effects: Equivalent to:
        return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last;

template<class RandomAccessIterator, class Compare>
    constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
    Effects: Equivalent to: return is_heap_until(first, last, comp) == last;

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
    bool is_heap(ExecutionPolicy&& exec,
                    RandomAccessIterator first, RandomAccessIterator last, Compare comp);
    Effects: Equivalent to:
        return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;

template<random_access_iterator I, sentinel_for<I> S, class Proj = identity, indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
    constexpr bool ranges::is_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Proj = identity, indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
    constexpr bool ranges::is_heap(R&& r, Comp comp = {}, Proj proj = {});

Effects: Equivalent to: return ranges::is_heap_until(first, last, comp, proj) == last;

template<class RandomAccessIterator>
    constexpr RandomAccessIterator
        is_heap_until(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
    RandomAccessIterator
        is_heap_until(ExecutionPolicy&& exec,
                        RandomAccessIterator first, RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
              Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
              RandomAccessIterator first, RandomAccessIterator last,
              Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Proj = identity,
         indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I
ranges::is_heap_until(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Proj = identity,
         indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::is_heap_until(R&& r, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.
Returns: The last iterator i in [first,last] for which the range [first,i) is a heap with respect to comp and proj.
Complexity: Linear.

27.8.9 Minimum and maximum [alg.min.max]

template<class T>
constexpr T min(const T& a, const T& b);

template<class T, class Compare>
constexpr T min(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
         indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T&
ranges::min(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
Returns: The smaller value. Returns the first argument when the arguments are equivalent.
Complexity: Exactly one comparison and two applications of the projection, if any.
Remarks: An invocation may explicitly specify an argument for the template parameter T of the
overloads in namespace std.

template<class T>
constexpr T min(initializer_list<T> r);

template<class T, class Compare>
constexpr T min(initializer_list<T> r, Compare comp);

template<copyable T, class Proj = identity,
         indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr T
ranges::min(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity,
         indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>>
ranges::min(R&& r, Comp comp = {}, Proj proj = {});

Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17-
CopyConstructible requirements. For the first form, T meets the Cpp17LessThanComparable requirements
(Table 29).
Returns: The smallest value in the input range. Returns a copy of the leftmost element when several
elements are equivalent to the smallest.
Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the
projection, if any.
Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

```cpp
template<class T>
    constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
    constexpr const T& max(const T& a, const T& b, Compare comp);
```

`template<class T, class Proj = identity, indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
    constexpr const T& ranges::max(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
```

Returns: The larger value. Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

```cpp
template<class T>
    constexpr T max(initializer_list<T> r);
template<class T, class Compare>
    constexpr T max(initializer_list<T> r, Compare comp);
```

`template<copyable T, class Proj = identity, indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
    constexpr T ranges::max(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity, indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
    requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>**>
    constexpr range_value_t<R>
    ranges::max(R&& r, Comp comp = {}, Proj proj = {});

Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17-CopyConstructible requirements. For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
```

Returns: The largest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the largest.

Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

```cpp
template<class T>
    constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
template<class T, class Compare>
    constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);
```

`template<class T, class Proj = identity, indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
    constexpr ranges::minmax_result<const T&>
    ranges::minmax(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
```

Returns: {b, a} if b is smaller than a, and {a, b} otherwise.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

```cpp
template<class T>
    constexpr pair<T, T> minmax(initializer_list<T> t);
```
template<class T, class Compare>
constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

template<copyable T, class Proj = identity,
indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<T>
ranges::minmax(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>>
constexpr ranges::minmax_result<range_value_t<R>>
ranges::minmax(R&& r, Comp comp = {}, Proj proj = {});

Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17-CopyConstructible requirements. For the first form, type T meets the Cpp17LessThanComparable requirements (Table 29).

Returns: Let X be the return type. Returns X{x, y}, where x is a copy of the leftmost element with the smallest value and y a copy of the rightmost element with the largest value in the input range.

Complexity: At most (3/2)ranges::distance(r) applications of the corresponding predicate and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator min_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator min_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, Compare comp);

Let comp be \texttt{less\{} and proj be \texttt{identity\{} for the overloads with no parameters by those names.

Returns: The first iterator i in the range \([\text{first}, \text{last})\) such that for every iterator \(j\) in the range \([\text{first}, \text{last})\),
\[\text{bool\{invoke(comp, invoke(proj, *j), invoke(proj, *i))}\] is false. Returns \texttt{last} if \texttt{first} == \texttt{last}.

Complexity: Exactly \(\text{max(largelast - first - 1, 0)}\) comparisons and twice as many projections.

template<class ForwardIterator>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator max_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last,
Compare comp);
template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator max_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::max_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R> ranges::max_element(R&& r, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Returns: The first iterator \( i \) in the range \([first, last)\) such that for every iterator \( j \) in the range \([first, last)\),
\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \ast i), \text{invoke}(\text{proj}, \ast j)))
\]
is false. Returns last if first == last.

Complexity: Exactly \( \max(last - first - 1, 0) \) comparisons and twice as many projections.

template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<I> ranges::minmax_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<borrowed_iterator_t<R>> ranges::minmax_element(R&& r, Comp comp = {}, Proj proj = {});

Returns: \{first, first\} if \([first, last)\) is empty, otherwise \(\{m, M\}\), where \( m \) is the first iterator in \([first, last)\) such that no iterator in the range refers to a smaller element, and where \( M \) is the last iterator\(^{217}\) in \([first, last)\) such that no iterator in the range refers to a larger element.

Complexity: Let \( N \) be last - first. At most \( \max\left(\left\lfloor \frac{3}{2}(N - 1)\right\rfloor, 0\right) \) comparisons and twice as many applications of the projection, if any.

27.8.10 Bounded value

[alg.clamp]

template<class T>
constexpr const T& clamp(const T& v, const T& lo, const T& hi);

template<class T, class Compare>
constexpr const T& clamp(const T& v, const T& lo, const T& hi, Compare comp);

\(^{217}\) This behavior intentionally differs from max_element.
template<class T, class Proj = identity,
        indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T&
ranges::clamp(const T& v, const T& lo, const T& hi, Comp comp = {}, Proj proj = {});

Let \( \text{comp} \) be \( \text{less}{} \) for the overloads with no parameter \( \text{comp} \), and let \( \text{proj} \) be \( \text{identity}{} \) for the overloads with no parameter \( \text{proj} \).

**Preconditions:** \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \text{hi}), \text{invoke}(\text{proj}, \text{lo}))) \) is \( \text{false} \). For the first form, type \( T \) meets the Cpp17LessThanComparable requirements (Table 29).

**Returns:** \( \text{lo} \) if \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \text{v}), \text{invoke}(\text{proj}, \text{lo}))) \) is \( \text{true} \), \( \text{hi} \) if \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \text{hi}), \text{invoke}(\text{proj}, \text{v}))) \) is \( \text{true} \), otherwise \( v \).

**[Note 1: If NaN is avoided, \( T \) can be a floating-point type. — end note]**

**Complexity:** At most two comparisons and three applications of the projection.

---

**27.8.11 Lexicographical comparison**

\[\text{alg.lex.comparison}\]

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool
lecxicographical_compare(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool
lecxicographical_compare(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool
lecxicographical_compare(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
Compare comp);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool
lecxicographical_compare(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
Compare comp);
```

```cpp
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, class Proj1 = identity, class Proj2 = identity,
indirect_strict_weak_order<projected<I1, Proj1>, projected<I2, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(I1 first1, S1 last1, I2 first2, S2 last2,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

```cpp
template<input_range R1, input_range R2, class Proj1 = identity, class Proj2 = identity,
indirect_strict_weak_order<projected<iterator_t<R1>, Proj1>, projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(R1&& r1, R2&& r2, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

**Returns:** \( \text{true} \) if and only if the sequence of elements defined by the range \([\text{first1}, \text{last1}]\) is lexicographically less than the sequence of elements defined by the range \([\text{first2}, \text{last2}]\).

**Complexity:** At most \( 2 \min(\text{last1} - \text{first1}, \text{last2} - \text{first2}) \) applications of the corresponding comparison and each projection, if any.

**Remarks:** If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a proper prefix of the other, then the shorter sequence is lexicographically less than the longer sequence.
Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

[Example 1: \texttt{ranges::lexicographical_compare(I1, S1, I2, S2, Comp, Proj1, Proj2)} can be implemented as:

```cpp
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
  if (invoke(comp, invoke(proj1, *first1), invoke(proj2, *first2))) return true;
  if (invoke(comp, invoke(proj2, *first2), invoke(proj1, *first1))) return false;
}
return first1 == last1 && first2 != last2;
```

—end example

[Note 1: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence. —end note]

27.8.12 Three-way comparison algorithms \[\text{alg.three.way}\]

```cpp
template<class InputIterator1, class InputIterator2, class Cmp>
constexpr auto lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
                                                InputIterator2 b2, InputIterator2 e2,
                                                Cmp comp) -> decltype(comp(*b1, *b2));
```

1 Let \( N \) be \( \text{min}(e1 - b1, e2 - b2) \). Let \( E(n) \) be \( \text{comp}(*\text{b1} + n, *\text{b2} + n) \).

2 \textbf{Mandates:} \text{decltype(comp(*b1, *b2))} is a comparison category type.

3 \textbf{Returns:} \( E(i) \), where \( i \) is the smallest integer in \([0, N)\) such that \( E(i) \) \(!=\) 0 is \text{true}, or \((e1 - b1) <=\) \((e2 - b2)\) if no such integer exists.

4 \textbf{Complexity:} At most \( N \) applications of \text{comp}.

```cpp
template<class InputIterator1, class InputIterator2>
constexpr auto lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
                                                InputIterator2 b2, InputIterator2 e2);
```

5 \textbf{Effects:} Equivalent to:

```cpp
return lexicographical_compare_three_way(b1, e1, b2, e2, compare_three_way());
```

27.8.13 Permutation generators \[\text{alg.permutation.generators}\]

```cpp
template<class BidirectionalIterator>
constexpr bool next_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool next_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last, Compare comp);
```

```cpp
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr ranges::next_permutation_result<I>
ranges::next_permutation(I first, S last, Comp comp = {}, Proj proj = {});
```

1 \textbf{Let comp be} \text{less{}} \text{and proj be} \text{identity{}} \text{for overloads with no parameters by those names.}

2 \textbf{Preconditions:} For the overloads in namespace std, \text{BidirectionalIterator} meets the Cpp17ValueSwappable requirements (16.4.4.3).

3 \textbf{Effects:} Takes a sequence defined by the range \([\text{first, last}]\) and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted
with respect to \( \text{comp} \) and \( \text{proj} \). If no such permutation exists, transforms the sequence into the first permutation; that is, the ascendingly-sorted one.

**Returns:** Let \( B \) be \text{true} if a next permutation was found and otherwise \text{false}. Returns:

\[ 4.1 \] \( B \) for the overloads in namespace \text{std}.

\[ 4.2 \] \{ \text{last}, B \} for the overloads in namespace \text{ranges}.

**Complexity:** At most \((\text{last} - \text{first}) / 2\) swaps.

```cpp
template<class BidirectionalIterator>
constexpr bool prev_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool prev_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last, Compare comp);
```

```cpp
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
ranges::prev_permutation_result<I>
ranges::prev_permutation(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<bidirectional_range R, class Comp = ranges::less,
         class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
ranges::prev_permutation_result<borrowed_iterator_t<R>>
ranges::prev_permutation(R&& r, Comp comp = {}, Proj proj = {});
```

Let \( \text{comp} \) be \text{less}{} and \( \text{proj} \) be \text{identity}{} for overloads with no parameters by those names.

**Preconditions:** For the overloads in namespace \text{std}, \text{BidirectionalIterator} meets the \text{Cpp17Value-Swappable} requirements (16.4.4.3).

**Effects:** Takes a sequence defined by the range \([\text{first}, \text{last})\) and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to \( \text{comp} \) and \( \text{proj} \). If no such permutation exists, transforms the sequence into the last permutation; that is, the descendingly-sorted one.

**Returns:** Let \( B \) be \text{true} if a previous permutation was found and otherwise \text{false}. Returns:

\[ 9.1 \] \( B \) for the overloads in namespace \text{std}.

\[ 9.2 \] \{ \text{last}, B \} for the overloads in namespace \text{ranges}.

**Complexity:** At most \((\text{last} - \text{first}) / 2\) swaps.

### 27.9 Header `<numeric>` synopsis

```cpp

27.10 Generalized numeric operations [numeric.ops]

27.10.1 General [numeric.ops.general]

1 [Note 1: The use of closed ranges as well as semi-open ranges to specify requirements throughout 27.10 is intentional.
—end note]

27.10.2 Definitions [numeric.deffns]

1 Define GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) as follows:

(1.1) — a1 when N is 1, otherwise

(1.2) — op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., ak),
  GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) for any K where 1 < K + 1 = M ≤ N.

2 Define GENERALIZED_SUM(op, a1, ..., aN) as GENERALIZED_NONCOMMUTATIVE_SUM(op, b1, ..., bN),
where b1, ..., bN may be any permutation of a1, ..., aN.

27.10.3 Accumulate [accumulate]

template<class InputIterator, class T>
    constexpr T accumulate(InputIterator first, InputIterator last, T init);

template<class InputIterator, class T, class BinaryOperation>
    constexpr T accumulate(InputIterator first, InputIterator last, T init,
        BinaryOperation binary_op);

1 Preconditions: T meets the Cpp17CopyConstructible (Table 32) and Cpp17CopyAssignable (Table 34)
requirements. In the range [first, last], binary_op neither modifies elements nor invalidates iterators
or subranges.218

2 Effects: Computes its result by initializing the accumulator acc with the initial value init and then
modifies it with acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) for every
iterator i in the range [first, last] in order.219

218) The use of fully closed ranges is intentional.
219) accumulate is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of
defining the result of reduction on an empty sequence by always requiring an initial value.
27.10.4 Reduce

```cpp
template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::value_type
reduce(InputIterator first, InputIterator last);
```

**Effects**: Equivalent to:

\[
\text{return reduce(first, last, }
\text{typename iterator_traits<InputIterator>::value_type());}
\]

```cpp
template<class ExecutionPolicy, class ForwardIterator>
typename iterator_traits<ForwardIterator>::value_type
reduce(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);
```

**Effects**: Equivalent to:

\[
\text{return reduce(std::forward<ExecutionPolicy>(exec), first, last, }
\text{typename iterator_traits<ForwardIterator>::value_type());}
\]

```cpp
template<class InputIterator, class T>
constexpr T reduce(InputIterator first, InputIterator last, T init);
```

**Effects**: Equivalent to:

\[
\text{return reduce(first, last, init, plus<>());}
\]

```cpp
template<class ExecutionPolicy, class ForwardIterator, class T>
T reduce(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, T init);
```

**Effects**: Equivalent to:

\[
\text{return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());}
\]

```cpp
template<class InputIterator, class T, class BinaryOperation>
constexpr T reduce(InputIterator first, InputIterator last, T init,
BinaryOperation binary_op);
```

**Mandates**: All of

- \(\text{binary_op(init, *first)},\)
- \(\text{binary_op(*first, init)},\)
- \(\text{binary_op(init, init)},\)
- \(\text{binary_op(*first, *first)}\)

are convertible to \(T\).

**Preconditions**:

- \(T\) meets the \textit{Cpp17MoveConstructible} (Table 31) requirements.
- \(\text{binary_op}\) neither invalidates iterators or subranges, nor modifies elements in the range \([\text{first, last}].\)

**Returns**: \textit{GENERALIZED\_SUM}(binary_op, init, *i, ...) for every \(i\) in \([\text{first, last}).\)

**Complexity**: \(\Theta(\text{last - first})\) applications of binary_op.

[Note 1: The difference between reduce and accumulate is that reduce applies binary_op in an unspecified order, which yields a nondeterministic result for non-associative or non-commutative binary_op such as floating-point addition. — end note]

27.10.5 Inner product

```cpp
template<class InputIterator1, class InputIterator2, class T>
constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, T init);
```

§ 27.10.5
template<class InputIterator1, class InputIterator2, class T,  
class BinaryOperation1, class BinaryOperation2>
constexpr T inner_product(InputIterator1 first1, InputIterator1 last1,  
InputIterator2 first2, T init,  
BinaryOperation1 binary_op1,  
BinaryOperation2 binary_op2);

1  **Preconditions**: T meets the `Cpp17CopyConstructible` (Table 32) and `Cpp17CopyAssignable` (Table 34) requirements. In the ranges `[first1, last1]` and `[first2, first2 + (last1 - first1)]` `binary_op1` and `binary_op2` neither modifies elements nor invalidates iterators or subranges.\(^{220}\)

2  **Effects**: Computes its result by initializing the accumulator `acc` with the initial value `init` and then modifying it with `acc = std::move(acc) + (*i1) * (*i2)` or `acc = binary_op1(std::move(acc), binary_op2(*i1, *i2))` for every iterator `i1` in the range `[first1, last1)` and iterator `i2` in the range `[first2, first2 + (last1 - first1))` in order.

27.10.6  **Transform reduce**

```cpp
template<class InputIterator1, class InputIterator2, class T>  
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,  
InputIterator2 first2,  
T init);
```

1  **Effects**: Equivalent to:

```cpp
return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());
```

```cpp
template<class ExecutionPolicy,  
class ForwardIterator1, class ForwardIterator2, class T>  
T transform_reduce(ExecutionPolicy&& exec,  
ForwardIterator1 first1, ForwardIterator1 last1,  
ForwardIterator2 first2,  
T init);
```

2  **Effects**: Equivalent to:

```cpp
return transform_reduce(std::forward<ExecutionPolicy>(exec),  
first1, last1, first2, init, plus<>(), multiplies<>());
```

```cpp
template<class InputIterator1, class InputIterator2, class T,  
class BinaryOperation1, class BinaryOperation2>  
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,  
InputIterator2 first2,  
T init,  
BinaryOperation1 binary_op1,  
BinaryOperation2 binary_op2);
```

```cpp
template<class ExecutionPolicy,  
class ForwardIterator1, class ForwardIterator2, class T,  
class BinaryOperation1, class BinaryOperation2>  
T transform_reduce(ExecutionPolicy&& exec,  
ForwardIterator1 first1, ForwardIterator1 last1,  
ForwardIterator2 first2,  
T init,  
BinaryOperation1 binary_op1,  
BinaryOperation2 binary_op2);
```

3  **Mandates**: All of

1. `binary_op1(init, init),`  
2. `binary_op1(init, binary_op2(*first1, *first2)),`  
3. `binary_op1(binary_op2(*first1, *first2), init),` and  
4. `binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))`

\(^{220}\) The use of fully closed ranges is intentional.
are convertible to $T$.

**Preconditions:**

(4.1) $T$ meets the Cpp17MoveConstructible (Table 31) requirements.

(4.2) Neither `binary_op1` nor `binary_op2` invalidates subranges, nor modifies elements in the ranges $[\text{first}1, \text{last}1]$ and $[\text{first}2, \text{first}2 + \text{(last}1 - \text{first}1)]$.

**Returns:**

$\text{GENERALIZED\_SUM}(\text{binary}\_\text{op1}, \text{init}, \text{binary}\_\text{op2}(*i, *(\text{first}2 + (i - \text{first}1))), \ldots)$

for every iterator $i$ in $[\text{first}1, \text{last}1]$.

**Complexity:** $O(\text{last}1 - \text{first}1)$ applications each of `binary_op1` and `binary_op2`.

```cpp
template<class InputIterator, class T, class BinaryOperation, class UnaryOperation>
constexpr T transform_reduce(InputIterator first, InputIterator last, T init,
   BinaryOperation binary_op, UnaryOperation unary_op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
   ForwardIterator first, ForwardIterator last,
   T init, BinaryOperation binary_op, UnaryOperation unary_op);
```

**Mandates:** All of

(7.1) `binary_op(init, init),`

(7.2) `binary_op(init, unary_op(*first)),`

(7.3) `binary_op(unary_op(*first), init), and`

(7.4) `binary_op(unary_op(*first), unary_op(*first))`

are convertible to $T$.

**Preconditions:**

(8.1) $T$ meets the Cpp17MoveConstructible (Table 31) requirements.

(8.2) Neither `unary_op` nor `binary_op` invalidates subranges, nor modifies elements in the range $[\text{first}, \text{last}].$

**Returns:**

$\text{GENERALIZED\_SUM}(\text{binary}\_\text{op}, \text{init}, \text{unary}\_\text{op}(\*i), \ldots)$

for every iterator $i$ in $[\text{first}, \text{last}].$

**Complexity:** $O(\text{last} - \text{first})$ applications each of `unary_op` and `binary_op`.

[Note 1: `transform_reduce` does not apply `unary_op` to `init`. — end note]

### 27.10.7 Partial sum

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator partial_sum(InputIterator first, InputIterator last,
   OutputIterator result);
```

```cpp
template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator partial_sum(InputIterator first, InputIterator last,
   OutputIterator result, BinaryOperation binary_op);
```

**Mandates:** `InputIterator`’s value type is constructible from `*first`. The result of the expression `std::move(acc) + *i` or `binary_op(std::move(acc), *i)` is implicitly convertible to `InputIterator`’s value type. $acc$ is writable (25.3.1) to $result$.

**Preconditions:** In the ranges $[\text{first}, \text{last}]$ and $[\text{result}, \text{result} + \text{(last} - \text{first})]$ `binary_op` neither modifies elements nor invalidates iterators or subranges.

221) The use of fully closed ranges is intentional.
**Effects:** For a non-empty range, the function creates an accumulator `acc` whose type is `InputIterator`'s value type, initializes it with `*first`, and assigns the result to `*result`. For every iterator `i` in `[first + 1, last)` in order, `acc` is then modified by `acc = std::move(acc) + *i` or `acc = binary_op(std::move(acc), *i)` and the result is assigned to `*(result + (i - first))`.

**Returns:** `result + (last - first)`.

**Complexity:** Exactly `last - first` - 1 applications of the binary operation.

**Remarks:** `result` may be equal to `first`.

## 27.10.8 Exclusive scan

### template<class InputIterator, class OutputIterator, class T>

```cpp
constexpr OutputIterator exclusive_scan(InputIterator first, InputIterator last, OutputIterator result, T init);```

**Effects:** Equivalent to:

```cpp
return exclusive_scan(first, last, result, init, plus<>());```

### template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>

```cpp
ForwardIterator2 exclusive_scan(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, T init);
```

**Effects:** Equivalent to:

```cpp
return exclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, init, plus<>());```

### template<class InputIterator, class OutputIterator, class T, class BinaryOperation>

```cpp
constexpr OutputIterator exclusive_scan(InputIterator first, InputIterator last, OutputIterator result, T init, BinaryOperation binary_op);```

### template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation>

```cpp
ForwardIterator2 exclusive_scan(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, T init, BinaryOperation binary_op);
```

**Mandates:** All of

1. `binary_op(init, init),`
2. `binary_op(init, *first),` and
3. `binary_op(*first, *first)`

are convertible to `T`.

**Preconditions:**
1. `T` meets the `Cpp17MoveConstructible` (Table 31) requirements.
2. `binary_op` neither invalidates iterators or subranges, nor modifies elements in the ranges `[first, last]` or `[result, result + (last - first)]`.

**Effects:** For each integer `K` in `[0, last - first)` assigns through `result + K` the value of:

`GENERALIZED_NONCOMMUTATIVE_SUM (binary_op, init, *(first + 0), *(first + 1), ..., *(first + K - 1))`

**Returns:** The end of the resulting range beginning at `result`.

**Complexity:** \(\Theta(last - first)\) applications of `binary_op`.

**Remarks:** `result` may be equal to `first`.

[Note 1: The difference between `exclusive_scan` and `inclusive_scan` is that `exclusive_scan` excludes the \(i\)th input element from the \(i\)th sum. If `binary_op` is not mathematically associative, the behavior of `exclusive_scan` can be nondeterministic. — end note]
27.10.9 Inclusive scan

```
    template<class InputIterator, class OutputIterator>
    constexpr OutputIterator
    inclusive_scan(InputIterator first, InputIterator last, OutputIterator result);
```

**Effects**: Equivalent to:
```
    return inclusive_scan(first, last, result, plus<>());
```

```
    template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result);
```

**Effects**: Equivalent to:
```
    return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());
```

```
    template<class InputIterator, class OutputIterator, class BinaryOperation>
    constexpr OutputIterator
    inclusive_scan(InputIterator first, InputIterator last, OutputIterator result, BinaryOperation binary_op);
```

```
    template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation>
    ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result, BinaryOperation binary_op);
```

```
    template<class InputIterator, class OutputIterator, class BinaryOperation, class T>
    constexpr OutputIterator
    inclusive_scan(InputIterator first, InputIterator last, OutputIterator result, BinaryOperation binary_op, T init);
```

```
    template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation, class T>
    ForwardIterator2
    inclusive_scan(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last,
                  ForwardIterator2 result, BinaryOperation binary_op, T init);
```

Let U be the value type of `decltype(first)`.

**Mandates**: If `init` is provided, all of

- `binary_op(init, init)`,
- `binary_op(init, *first)`, and
- `binary_op(*first, *first)`

are convertible to `T`; otherwise, `binary_op(*first, *first)` is convertible to `U`.

**Preconditions**:

- If `init` is provided, `T` meets the `Cpp17MoveConstructible` (Table 31) requirements; otherwise, `U` meets the `Cpp17MoveConstructible` requirements.
- `binary_op` neither invalidates iterators or subranges, nor modifies elements in the ranges `[first, last]` or `[result, result + (last - first)]`.

**Effects**: For each integer `K` in `[0, last - first)` assigns through `result + K` the value of

- `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, *(first + 1), ..., *(first + K))` if `init` is provided, or
- `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, *(first + 0), *(first + 1), ..., *(first + K))` otherwise.
Returns: The end of the resulting range beginning at \texttt{result}.

Complexity: \(O(last - first)\) applications of \texttt{binary_op}.

Remarks: result may be equal to \texttt{first}.

[Note 1: The difference between \texttt{exclusive_scan} and \texttt{inclusive_scan} is that \texttt{inclusive_scan} includes the \(i^{th}\) input element in the \(i^{th}\) sum. If \texttt{binary_op} is not mathematically associative, the behavior of \texttt{inclusive_scan} can be nondeterministic. — end note]

27.10.10 Transform exclusive scan

\begin{verbatim}
template<class InputIterator, class OutputIterator, class T,
         class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
transform_exclusive_scan(InputIterator first, InputIterator last,
                          OutputIterator result, T init,
                          BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2, class T,
         class BinaryOperation, class UnaryOperation>
ForwardIterator2
transform_exclusive_scan(ExecutionPolicy&& exec,
                        ForwardIterator1 first, ForwardIterator1 last,
                        ForwardIterator2 result, T init,
                        BinaryOperation binary_op, UnaryOperation unary_op);
\end{verbatim}

Mandates: All of
\begin{enumerate}
\item[(1.1)] \texttt{binary_op(init, init)},
\item[(1.2)] \texttt{binary_op(init, unary_op(*first))}, and
\item[(1.3)] \texttt{binary_op(unary_op(*first), unary_op(*first))}
\end{enumerate}
are convertible to \texttt{T}.

Preconditions:
\begin{enumerate}
\item[(2.1)] \texttt{T} meets the \texttt{Cpp17MoveConstructible} (Table 31) requirements.
\item[(2.2)] Neither \texttt{unary_op} nor \texttt{binary_op} invalidates iterators or subranges, nor modifies elements in the ranges \([first, last]\) or \([result, result + (last - first)]\).
\end{enumerate}

Effects: For each integer \(K\) in \([0, last - first]\) assigns through \texttt{result + K} the value of:
\[
\texttt{GENERALIZED_NONCOMMUTATIVE_SUM} \texttt{binary_op, init,}
\texttt{unary_op(*first + 0)}, \texttt{unary_op(*first + 1)}, \ldots, \texttt{unary_op(*first + K - 1))}
\]

Returns: The end of the resulting range beginning at \texttt{result}.

Complexity: \(O(last - first)\) applications each of \texttt{unary_op} and \texttt{binary_op}.

Remarks: result may be equal to \texttt{first}.

[Note 1: The difference between \texttt{transform_exclusive_scan} and \texttt{transform_inclusive_scan} is that \texttt{transform_exclusive_scan} excludes the \(i^{th}\) input element from the \(i^{th}\) sum. If \texttt{binary_op} is not mathematically associative, the behavior of \texttt{transform_exclusive_scan} can be nondeterministic. \texttt{transform_exclusive_scan} does not apply \texttt{unary_op} to \texttt{init}. — end note]

27.10.11 Transform inclusive scan

\begin{verbatim}
template<class InputIterator, class OutputIterator,
         class BinaryOperation, class UnaryOperation>
constexpr OutputIterator
transform_inclusive_scan(InputIterator first, InputIterator last,
                         OutputIterator result,
                         BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
         class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation, class UnaryOperation>
ForwardIterator2
transform_inclusive_scan(ExecutionPolicy&& exec,
                       ForwardIterator1 first, ForwardIterator1 last,
                       ForwardIterator2 result,
                       BinaryOperation binary_op, UnaryOperation unary_op);
\end{verbatim}
transform_inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
    BinaryOperation binary_op, UnaryOperation unary_op);

-template<class InputIterator, class OutputIterator,
    class BinaryOperation, class UnaryOperation, class T>
    constexpr OutputIterator
    transform_inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op, UnaryOperation unary_op,
    T init);

-template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2,
    class BinaryOperation, class UnaryOperation, class T>
    ForwardIterator2
    transform_inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
    BinaryOperation binary_op, UnaryOperation unary_op,
    T init);

1 Let U be the value type of decltype(first).
2
2.1 Mandates: If init is provided, all of
   — binary_op(init, init),
   — binary_op(init, unary_op(*first)), and
   — binary_op(unary_op(*first), unary_op(*first))

          are convertible to T; otherwise, binary_op(unary_op(*first), unary_op(*first)) is convertible to U.
3
3.1 Preconditions:
   — If init is provided, T meets the Cpp17MoveConstructible (Table 31) requirements; otherwise, U meets the Cpp17MoveConstructible requirements.
   — Neither unary_op nor binary_op invalidates iterators or subranges, nor modifies elements in the ranges [first, last) or [result, result + (last - first)].
4
4.1 Effects: For each integer K in [0, last - first) assigns through result + K the value of
   — GENERALIZED_NONCOMMUTATIVE_SUM
       binary_op, init,
       unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K))
       if init is provided, or
   — GENERALIZED_NONCOMMUTATIVE_SUM
       binary_op,
       unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K))
       otherwise.
5
5.1 Returns: The end of the resulting range beginning at result.
6
6.1 Complexity: O(last - first) applications each of unary_op and binary_op.
7
7.1 Remarks: result may be equal to first.
8
8.1 [Note 1: The difference between transform-exclusive_scan and transform-inclusive_scan is that transform-inclusive_scan includes the i-th input element in the i-th sum. If binary_op is not mathematically associative, the behavior of transform-inclusive_scan can be nondeterministic. transform-inclusive_scan does not apply unary_op to init. — end note]

27.10.12 Adjacent difference [adjacent.difference]

-template<class InputIterator, class OutputIterator>
    constexpr OutputIterator
    adjacent_difference(InputIterator first, InputIterator last,
    OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, BinaryOperation binary_op);

Let \( T \) be the value type of \( \text{decltype}(\text{first}) \). For the overloads that do not take an argument \( \text{binary\_op} \), let \( \text{binary\_op} \) be an lvalue that denotes an object of type \( \text{minus<>()} \).

**Mandates:**

1. For the overloads with no \( \text{ExecutionPolicy} \), \( T \) is constructible from \( \ast\text{first} \). \( \text{acc} \) (defined below) is writable (25.3.1) to the result output iterator. The result of the expression \( \text{binary\_op}(\text{val}, \text{std::move}(\text{acc})) \) is writable to result.

2. For the overloads with an \( \text{ExecutionPolicy} \), the result of the expressions \( \text{binary\_op}(\ast\text{first}, \ast\text{first}) \) and \( \ast\text{first} \) are writable to result.

**Preconditions:**

1. For the overloads with no \( \text{ExecutionPolicy} \), \( T \) meets the \( \text{Cpp17MoveAssignable} \) (Table 33) requirements.

2. For all overloads, in the ranges \([\text{first}, \text{last}]\) and \([\text{result.result + (last - first)}] \), \( \text{binary\_op} \) neither modifies elements nor invalidates iterators or subranges.\(^{222}\)

**Effects:** For the overloads with no \( \text{ExecutionPolicy} \) and a non-empty range, the function creates an accumulator \( \text{acc} \) of type \( T \), initializes it with \( \ast\text{first} \), and assigns the result to \( \ast\text{result} \). For every iterator \( i \) in \([\text{first + 1}, \text{last})\) in order, creates an object \( \text{val} \) whose type is \( T \), initializes it with \( \ast i \), computes \( \text{binary\_op}(\text{val}, \text{std::move}(\text{acc})) \), assigns the result to \( \ast(\text{result} + (i - \text{first})) \), and move assigns from \( \text{val} \) to \( \text{acc} \).

For the overloads with an \( \text{ExecutionPolicy} \) and a non-empty range, performs \( \ast\text{result} = \ast\text{first} \). Then, for every \( d \) in \([1, \text{last - first - 1}] \), performs \( \ast(\text{result} + d) = \text{binary\_op}(\ast(\text{first} + d), \ast(\text{first} + (d - 1))) \).

**Returns:** \( \text{result + (last - first)} \).

**Complexity:** Exactly \( \text{last - first} - 1 \) applications of the binary operation.

**Remarks:** For the overloads with no \( \text{ExecutionPolicy} \), \( \text{result} \) may be equal to \( \text{first} \). For the overloads with an \( \text{ExecutionPolicy} \), the ranges \([\text{first}, \text{last}] \) and \([\text{result.result + (last - first)}] \) shall not overlap.

### 27.10.13 Iota

`template<class ForwardIterator, class T>
constexpr void iota(ForwardIterator first, ForwardIterator last, T value);`

**Mandates:** \( T \) is convertible to \( \text{ForwardIterator} \)'s value type. The expression \( ++\text{val} \), where \( \text{val} \) has type \( T \), is well-formed.

**Effects:** For each element referred to by the iterator \( i \) in the range \([\text{first}, \text{last}] \), assigns \( \ast i = \text{value} \) and increments \( \text{value} \) as if by \( ++\text{value} \).

**Complexity:** Exactly \( \text{last - first} \) increments and assignments.

\(^{222}\) The use of fully closed ranges is intentional.
template<input_or_output_iterator O, sentinel_for<O> S, weakly_incrementable T>
requires indirectly_writable<O, const T&>
constexpr ranges::iota_result<O, T> ranges::iota(O first, S last, T value);

template<weakly_incrementable T, output_range<const T&> R>
constexpr ranges::iota_result<borrowed_iterator_t<R>, T> ranges::iota(R&& r, T value);

Effects: Equivalent to:
while (first != last) {
    *first = as_const(value);
    ++first;
    ++value;
}
return {std::move(first), std::move(value)};

27.10.14 Greatest common divisor
[numeric.ops.gcd]

template<class M, class N>
constexpr common_type_t<M, N> gcd(M m, N n);

Mandates: M and N both are integer types other than cv bool.
Preconditions: |m| and |n| are representable as a value of common_type_t<M, N>.
[Note 1: These requirements ensure, for example, that gcd(m, m) = |m| is representable as a value of type M.
—end note]
Returns: Zero when m and n are both zero. Otherwise, returns the greatest common divisor of |m| and |n|.
Throws: Nothing.

27.10.15 Least common multiple
[numeric.ops.lcm]

template<class M, class N>
constexpr common_type_t<M, N> lcm(M m, N n);

Mandates: M and N both are integer types other than cv bool.
Preconditions: |m| and |n| are representable as a value of common_type_t<M, N>. The least common
multiple of |m| and |n| is representable as a value of type common_type_t<M, N>.
Returns: Zero when either m or n is zero. Otherwise, returns the least common multiple of |m| and |n|.
Throws: Nothing.

27.10.16 Midpoint
[numeric.ops.midpoint]

template<class T>
constexpr T midpoint(T a, T b) noexcept;

Constraints: T is an arithmetic type other than bool.
Returns: Half the sum of a and b. If T is an integer type and the sum is odd, the result is rounded
towards a.
Remarks: No overflow occurs. If T is a floating-point type, at most one inexact operation occurs.

template<class T>
constexpr T* midpoint(T* a, T* b);

Constraints: T is an object type.
Mandates: T is a complete type.
Preconditions: a and b point to, respectively, elements i and j of the same array object x.
[Note 1: As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element
array for this purpose and a pointer past the last element of an array of n elements is considered to be equivalent
to a pointer to a hypothetical array element n for this purpose. —end note]
Returns: A pointer to array element i + \frac{j-i}{2} of x, where the result of the division is truncated towards
zero.
27.10.17 Saturation arithmetic [numeric.sat]

27.10.17.1 Arithmetic functions [numeric.sat.func]

[Note 1: In the following descriptions, an arithmetic operation is performed as a mathematical operation with infinite range and then it is determined whether the mathematical result fits into the result type. — end note]

```cpp
template<class T>
constexpr T add_sat(T x, T y) noexcept;
```

Constraints: T is a signed or unsigned integer type (6.8.2).

Returns: If \( x + y \) is representable as a value of type T, \( x + y \); otherwise, either the largest or smallest representable value of type T, whichever is closer to the value of \( x + y \).

```cpp
template<class T>
constexpr T sub_sat(T x, T y) noexcept;
```

Constraints: T is a signed or unsigned integer type (6.8.2).

Returns: If \( x - y \) is representable as a value of type T, \( x - y \); otherwise, either the largest or smallest representable value of type T, whichever is closer to the value of \( x - y \).

```cpp
template<class T>
constexpr T mul_sat(T x, T y) noexcept;
```

Constraints: T is a signed or unsigned integer type (6.8.2).

Returns: If \( x \times y \) is representable as a value of type T, \( x \times y \); otherwise, either the largest or smallest representable value of type T, whichever is closer to the value of \( x \times y \).

```cpp
template<class T>
constexpr T div_sat(T x, T y) noexcept;
```

Constraints: T is a signed or unsigned integer type (6.8.2).

Preconditions: \( y \neq 0 \) is true.

Returns: If T is a signed integer type and \( x == \text{numeric_limits<T>::min()} \&\& y == -1 \) is true, \( \text{numeric_limits<T>::max()} \), otherwise, \( x / y \).

Remarks: A function call expression that violates the precondition in the Preconditions element is not a core constant expression (7.7).

27.10.17.2 Casting [numeric.sat.cast]

```cpp
template<class R, class T>
constexpr R saturate_cast(T x) noexcept;
```

Constraints: R and T are signed or unsigned integer types (6.8.2).

Returns: If x is representable as a value of type R, x; otherwise, either the largest or smallest representable value of type R, whichever is closer to the value of x.

27.11 Specialized <memory> algorithms [specialized.algorithms]

27.11.1 General [specialized.algorithms.general]

The contents specified in 27.11 are declared in the header <memory> (20.2.2).

Unless otherwise specified, if an exception is thrown in the following algorithms, objects constructed by a placement new-expression (7.6.2.8) are destroyed in an unspecified order before allowing the exception to propagate.

Some algorithms specified in 27.11 make use of the exposition-only function template `voidify`:

```cpp
template<class T>
constexpr void* voidify(T& obj) noexcept {
    return addressof(obj);
}
```

27.11.2 Special memory concepts [special.mem.concepts]

Some algorithms in this subclause are constrained with the following exposition-only concepts:
template<class I>
concept noexcept-input_iterator = // exposition only
    input_iterator<I> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<remove_cvref_t<iter_reference_t<I>>, iter_value_t<I>>;

A type I models noexcept-input_iterator only if no exceptions are thrown from increment, copy construction, move construction, copy assignment, move assignment, or indirection through valid iterators.

[Note 1: This concept allows some input_iterator (25.3.4.9) operations to throw exceptions. — end note]

template<class S, class I>
concept noexcept-sentinel-for = sentinel_for<S, I>; // exposition only

Types S and I model noexcept-sentinel-for only if no exceptions are thrown from copy construction, move construction, copy assignment, move assignment, or comparisons between valid values of type I and S.

[Note 2: This concept allows some sentinel_for (25.3.4.7) operations to throw exceptions. — end note]

template<class R>
concept noexcept-input-range = // exposition only
    range<R> &&
    noexcept-input-iterator<iterator_t<R>> &&
    noexcept-sentinel-for<sentinel_t<R>, iterator_t<R>>;

A type R models noexcept-input-range only if no exceptions are thrown from calls to ranges::begin and ranges::end on an object of type R.

template<class I>
concept noexcept-forward-iterator = // exposition only
    noexcept-input-iterator<I> &&
    forward_iterator<I> &&
    noexcept-sentinel-for<I, I>;

[Note 3: This concept allows some forward_iterator (25.3.4.11) operations to throw exceptions. — end note]

template<class R>
concept noexcept-forward-range = // exposition only
    noexcept-input-range<R> &&
    noexcept-forward-iterator<iterator_t<R>>;

27.11.3 uninitialized_default_construct [uninitialized.construct.default]

template<class NoThrowForwardIterator>
void uninitialized_default_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);

Effects: Equivalent to:

```cpp
for (; first != last; ++first)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type;
```

namespace ranges {
    template<nothrow-forward-iterator I, noexcept-sentinel-for<I> S>
        requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct(I first, S last);
    template<nothrow-forward-range R>
        requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_default_construct(R&& r);
}

Effects: Equivalent to:

```cpp
for (; first != last; ++first)
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>;
    return first;
```
template<class NoThrowForwardIterator, class Size>
NoThrowForwardIterator uninitialized_default_construct_n(NoThrowForwardIterator first, Size n);

Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
    NEW (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type;
return first;

amespace ranges {
    template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct_n(I first, iter_difference_t<I> n);
}

27.11.4 uninitialized_value_construct
[uninitialized.construct.value]

template<class NoThrowForwardIterator>
void uninitialized_value_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);

Effects: Equivalent to:
for (; first != last; ++first)
    NEW (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();

namespace ranges {
    template<nothrow-forward-iterator I, noexcept-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct(I first, S last);
    template<nothrow-forward-range R>
    requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_value_construct(R&& r);
}

Effects: Equivalent to:
for (; first != last; ++first)
    NEW (voidify(*first)) remove_reference_t<iter_reference_t<I>>()
    return first;

namespace ranges {
    template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct_n(I first, iter_difference_t<I> n);
}

Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
    NEW (voidify(*first))
    typename iterator_traits<NoThrowForwardIterator>::value_type();
return first;

namespace ranges {
    template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct_n(I first, iter_difference_t<I> n);
}

Effects: Equivalent to:
return uninitialized_value_construct(counted_iterator(first, n),
    default_sentinel).base();

27.11.5 uninitialized_copy
[uninitialized.copy]

§ 27.11.5 1425
template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
NoThrowForwardIterator result);

Preconditions: result + |0, (last - first)| does not overlap with [first, last).

Effects: Equivalent to:

for (; first != last; ++result, (void) ++first)
    ::new (voidify(*result))
    typename iterator_traits<NoThrowForwardIterator>::value_type(*first);

Returns: result.

namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
            nothrow-forward_iterator O, nothrow-sentinel-for<O> S2>
    requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);
    template<input_range IR, nothrow-forward-range OR>
    requires constructible_from<range_value_t<OR>, range_reference_t<IR>>
    uninitialized_copy_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
    uninitialized_copy(IR&& in_range, OR&& out_range);
}

Preconditions: [ofirst,olast) does not overlap with [ifirst,ilast).

Effects: Equivalent to:

for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst)
    ::new (voidify(*ofirst)) remove_reference_t<iter_reference_t<O>>(*ifirst);
return {std::move(ifirst), ofirst};

template<class InputIterator, class Size, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy_n(InputIterator first, Size n,
NoThrowForwardIterator result);

Preconditions: result + |0, n| does not overlap with first + |0, n|.

Effects: Equivalent to:

for ( ; n > 0; ++result, (void) ++first, --n)
    ::new (voidify(*result))
    typename iterator_traits<NoThrowForwardIterator>::value_type(*first);

Returns: result.

namespace ranges {
    template<input_iterator I, nothrow-forward_iterator O, nothrow-sentinel-for<O> S>
    requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy_n_result<I, O>
    uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

Preconditions: [ofirst,olast) does not overlap with ifirst + |0, n|.

Effects: Equivalent to:

auto t = uninitialized_copy(counted_iterator(std::move(ifirst), n),
    default_sentinel, ofirst, olast);
return {std::move(t.in).base(), t.out};

27.11.6 uninitialized_move

[uninitialized.move]

template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_move(InputIterator first, InputIterator last,
NoThrowForwardIterator result);

Preconditions: result + |0, (last - first)| does not overlap with [first, last).

Effects: Equivalent to:

§ 27.11.6 1426
for (; first != last; (void)++result, ++first)
    :new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
    return result;

namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
        nothrow-forward_iterator 0, nothrow-sentinel_for<O> S2>
    requires constructible_from<iter_value_t<I>, iter_rvalue_reference_t<I>>
    uninitialized_move_result<I, O>
    uninitialized_move(I ifirst, S1 ilast, 0 ofirst, S2 olast);
    template<input_range IR, nothrow-forward-range OR>
    requires constructible_from<range_value_t<OR>, range_rvalue_reference_t<IR>>
    uninitialized_move_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
    uninitialized_move(IR&& in_range, OR&& out_range);
}

3  Preconditions: (ofirst, olast) does not overlap with (ifirst, ilast).
4  Effects: Equivalent to:
            for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst)
                :new (voidify(*ofirst))
                    remove_reference_t<iter_reference_t<O>>(ranges::iter_move(ifirst));
    return {std::move(ifirst), ofirst};

5  [Note 1: If an exception is thrown, some objects in the range (ifirst, ilast) are left in a valid, but unspecified state. — end note]

template<class InputIterator, class Size, class NoThrowForwardIterator>
    pair<InputIterator, NoThrowForwardIterator>
    uninitialized_move_n(InputIterator first, Size n, NoThrowForwardIterator result);

6  Preconditions: result + [0, n) does not overlap with first + [0, n).
7  Effects: Equivalent to:
            for (; n > 0; ++result, (void) ++first, --n)
                :new (voidify(*result))
                    typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
    return {first, result};

namespace ranges {
    template<input_iterator I, nothrow-forward_iterator 0, nothrow-sentinel_for<O> S>
    requires constructible_from<iter_value_t<I>, iter_rvalue_reference_t<I>>
    uninitialized_move_n_result<I, O>
    uninitialized_move_n(I ifirst, iter_difference_t<I> n, 0 ofirst, S olast);
}

8  Preconditions: (ofirst, olast) does not overlap with ifirst + [0, n).
9  Effects: Equivalent to:
            auto t = uninitialized_move(counted_iterator(std::move(ifirst), n),
                default_sentinel, ofirst, olast);
    return {std::move(t.in).base(), t.out};

10 [Note 2: If an exception is thrown, some objects in the range ifirst + [0, n) are left in a valid but unspecified state. — end note]

27.11.7 uninitialized_fill

template<class NoThrowForwardIterator, class T>
    void uninitialized_fill(NoThrowForwardIterator first, NoThrowForwardIterator last, const T& x);
1  Effects: Equivalent to:
            for (; first != last; ++first)
                :new (voidify(*first))
                    typename iterator_traits<NoThrowForwardIterator>::value_type(x);
namespace ranges {
    template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S, class T>
    requires constructible_from<iter_value_t<I>, const T&>
    I uninitialized_fill(I first, S last, const T& x);
    template<nothrow-forward-range R, class T>
    requires constructible_from<range_value_t<R>, const T&>
    borrowed_iterator_t<R> uninitialized_fill(R&& r, const T& x);
}

Effects: Equivalent to:
for (; first != last; ++first)
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>(x);
return first;

namespace ranges {
    template<class NoThrowForwardIterator, class Size, class T>
    NoThrowForwardIterator uninitialized_fill_n(NoThrowForwardIterator first, Size n, const T& x);
}

Effects: Equivalent to:
for (; n--; ++first)
    ::new (voidify(*first)) typename iterator_traits<NoThrowForwardIterator>::value_type(x);
return first;

namespace ranges {
    template<nothrow-forward-iterator I, class T>
    requires constructible_from<iter_value_t<I>, const T&>
    I uninitialized_fill_n(I first, iter_difference_t<I> n, const T& x);
}

Effects: Equivalent to:
return uninitialized_fill(counted_iterator(first, n), default_sentinel, x).base();

27.11.8 construct_at
    [specialized.construct]

template<class T, class... Args>
    constexpr T* construct_at(T* location, Args&&... args);

namespace ranges {
    template<class T, class... Args>
    constexpr T* construct_at(T* location, Args&&... args);
}

1 Constraints: The expression ::new (declval<void*>()) T(declval<Args>()...) is well-formed when treated as an unevaluated operand (7.2.3).

2 Effects: Equivalent to:
return ::new (voidify(*location)) T(std::forward<Args>(args)...);

27.11.9 destroy
    [specialized.destroy]

template<class T>
    constexpr void destroy_at(T* location);

namespace ranges {
    template<destructible T>
    constexpr void destroy_at(T* location) noexcept;
}

1 Effects:
(1.1) If T is an array type, equivalent to destroy(begin(*location), end(*location)).
(1.2) Otherwise, equivalent to location->~T().

template<class NoThrowForwardIterator>
    constexpr void destroy(NoThrowForwardIterator first, NoThrowForwardIterator last);

2 Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));

namespace ranges {
    template<nothrow-input-iterator I, nothrow-sentinel-for<I> S>
    requires destructible<iter_value_t<I>>
    constexpr I destroy(I first, S last) noexcept;
    template<nothrow-input-range R>
    requires destructible<range_value_t<R>>
    constexpr borrowed_iterator_t<R> destroy(R&& r) noexcept;
}

3
Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));
return first;

namespace ranges {
    template<class NoThrowForwardIterator, class Size>
    constexpr NoThrowForwardIterator destroy_n(NoThrowForwardIterator first, Size n);
}

4
Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
    destroy_at(addressof(*first));
return first;

namespace ranges {
    template<nothrow-input-iterator I>
    requires destructible<iter_value_t<I>>
    constexpr I destroy_n(I first, iter_difference_t<I> n) noexcept;
}

5
Effects: Equivalent to:
return destroy(counted_iterator(std::move(first), n), default_sentinel).base();

27.12 C library algorithms

1 [Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

    void* bsearch(const void* key, const void* base, size_t nmem, size_t size,
                  c-compare-pred* compar);
    void* bsearch(const void* key, const void* base, size_t nmem, size_t size,
                  compare-pred* compar);
    void qsort(void* base, size_t nmem, size_t size, c-compare-pred* compar);
    void qsort(void* base, size_t nmem, size_t size, compare-pred* compar);

2 Preconditions: For qsort, the objects in the array pointed to by base are of trivially copyable type.

3 Effects: These functions have the semantics specified in the C standard library.

4 Throws: Any exception thrown by compar (16.4.6.13).

See also: ISO/IEC 9899:2018, 7.22.5
28  Numerics library

28.1  General

This Clause describes components that C++ programs may use to perform seminumerical operations.

The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical constants and functions for floating-point types, as summarized in Table 94.

Table 94 — Numerics library summary

<table>
<thead>

<tr>
<td>28.9</td>
<td></td>
</tr>
</tbody>
</table>

28.2  Numeric type requirements

The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a numeric type. A numeric type is a cv-unqualified object type \( T \) that meets the Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements (16.4.4.2).

If any operation on \( T \) throws an exception the effects are undefined.

In addition, many member and related functions of valarray\(\langle T\rangle \) can be successfully instantiated and will exhibit well-defined behavior if and only if \( T \) meets additional requirements specified for each such member or related function.

[Example 1: It is valid to instantiate valarray<complex>, but operator() will not be successfully instantiated for valarray<complex> operands, since complex does not have any ordering operators. — end example]

28.3  The floating-point environment

28.3.1  Header <cfenv>

#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below  // optional
#define FE_INEXACT see below     // optional
#define FE_INVALID see below     // optional
#define FE_OVERFLOW see below    // optional
#define FE_UNDERFLOW see below   // optional
#define FE_DOWNWARD see below    // optional
#define FE_TONEAREST see below   // optional
#define FE_TOWARDZERO see below  // optional
#define FE_UPWARD see below      // optional
#define FE_DFL_ENV see below     // optional

223) In other words, value types. These include arithmetic types, pointers, the library class complex, and instantiations of valarray for value types.
namespace std {
    // types
    using fenv_t = object type;
    using fexcept_t = object type;

    // functions
    int feclearexcept(int except);
    int fegetexceptflag(fexcept_t* pflag, int except);
    int feraiseexcept(int except);
    int fesetexceptflag(const fexcept_t* pflag, int except);
    int fetestexcept(int except);
    int fegetround();
    int fesetround(int mode);
    int fegetenv(fenv_t* penv);
    int feholdexcept(fenv_t* penv);
    int fesetenv(const fenv_t* penv);
    int feupdateenv(const fenv_t* penv);
}

1 The contents and meaning of the header <cfenv> are the same as the C standard library header <fenv.h>.

[Note 1: This document does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (15.9) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions. — end note]

See also: ISO/IEC 9899:2018, 7.6

28.3.2 Threads [cfenv.thread]

1 The floating-point environment has thread storage duration (6.7.5.3). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (33.4.3) or jthread object (33.4.4) at the time it constructed the object.

[Note 1: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. — end note]

2 A separate floating-point environment is maintained for each thread. Each function accesses the environment corresponding to its calling thread.

28.4 Complex numbers [complex.numbers]

28.4.1 General [complex.numbers.general]

1 The header <complex> defines a class template, and numerous functions for representing and manipulating complex numbers.

2 The effect of instantiating the template complex for any type that is not a cv-unqualified floating-point type (6.8.2) is unspecified. Specializations of complex for cv-unqualified floating-point types are trivially copyable literal types (6.8.1).

3 If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

4 If z is an lvalue of type cv complex<T> then:

(4.1) — the expression reinterpret_cast<cv T(&)[2]>(z) is well-formed,
(4.2) — reinterpret_cast<cv T(&)[2]>(z)[0] designates the real part of z, and
(4.3) — reinterpret_cast<cv T(&)[2]>(z)[1] designates the imaginary part of z.

Moreover, if a is an expression of type cv complex<T> and the expression a[i] is well-defined for an integer expression i, then:

(4.4) — reinterpret_cast<cv T*>(a)[2*i] designates the real part of a[i], and
(4.5) — reinterpret_cast<cv T*>(a)[2*i + 1] designates the imaginary part of a[i].
28.4.2 Header <complex> synopsis

namespace std {
    // 28.4.3, class template complex
    template<class T> class complex;

    // 28.4.6, operators
    template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
    template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
    template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);
    template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
    template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);
    template<class T> constexpr complex<T> operator-(const T&, const complex<T>&);
    template<class T> constexpr complex<T> operator*(const complex<T>&, const complex<T>&);
    template<class T> constexpr complex<T> operator*(const complex<T>&, const T&);
    template<class T> constexpr complex<T> operator*(const T&, const complex<T>&);
    template<class T> constexpr complex<T> operator/(const complex<T>&, const complex<T>&);
    template<class T> constexpr complex<T> operator/(const complex<T>&, const T&);
    template<class T> constexpr complex<T> operator/(const T&, const complex<T>&);

        constexpr complex<long double> operator""il(unsigned long long);
        constexpr complex<double> operator""i(long double);
        constexpr complex<double> operator""i(unsigned long long);
    }
}

28.4.3 Class template complex

namespace std {
    template<class T> class complex {
public:
        using value_type = T;
        constexpr complex(const T& re = T(), const T& im = T());
        constexpr complex(const complex&) = default;
        template<class X> constexpr explicit(see below) complex(const complex<X>&);

        constexpr T real() const;
        constexpr void real(T);
        constexpr T imag() const;
        constexpr void imag(T);

        constexpr complex& operator= (const T&);
        constexpr complex& operator+=(const T&);
        constexpr complex& operator-=(const T&);
        constexpr complex& operator*=(const T&);
        constexpr complex& operator/=(const T&);
        template<class X> constexpr complex& operator= (const complex<X>&);
        template<class X> constexpr complex& operator+=(const complex<X>&);
        template<class X> constexpr complex& operator-=(const complex<X>&);
        template<class X> constexpr complex& operator*=(const complex<X>&);
        template<class X> constexpr complex& operator/=(const complex<X>&);
    };
}
The class `complex` describes an object that can store the Cartesian components, \( \text{real}() \) and \( \text{imag}() \), of a complex number.

### 28.4.4 Member functions

```cpp
constexpr complex(const T& re = T(), const T& im = T());
```

*Postconditions:* \( \text{real}() == \text{re} \&\& \text{imag}() == \text{im} \) is true.

```cpp
template<class X> constexpr explicit(const complex<X>& other);
```

*Effects:* Initializes the real part with \( \text{other}.\text{real}() \) and the imaginary part with \( \text{other}.\text{imag}() \).

*Remarks:* The expression inside `explicit` evaluates to `false` if and only if the floating-point conversion rank of \( T \) is greater than or equal to the floating-point conversion rank of \( X \).

```cpp
constexpr T real() const;
```

*Returns:* The value of the real component.

```cpp
constexpr void real(T val);
```

*Effects:* Assigns \( \text{val} \) to the real component.

```cpp
constexpr T imag() const;
```

*Returns:* The value of the imaginary component.

```cpp
constexpr void imag(T val);
```

*Effects:* Assigns \( \text{val} \) to the imaginary component.

### 28.4.5 Member operators

```cpp
constexpr complex& operator+=(const T& rhs);
```

*Effects:* Adds the scalar value \( \text{rhs} \) to the real part of the complex value \(*\text{this}\) and stores the result in the real part of \(*\text{this}\), leaving the imaginary part unchanged.

*Returns:* \(*\text{this}\).

```cpp
constexpr complex& operator-=(const T& rhs);
```

*Effects:* Subtracts the scalar value \( \text{rhs} \) from the real part of the complex value \(*\text{this}\) and stores the result in the real part of \(*\text{this}\), leaving the imaginary part unchanged.

*Returns:* \(*\text{this}\).

```cpp
constexpr complex& operator*=(const T& rhs);
```

*Effects:* Multiplies the scalar value \( \text{rhs} \) by the complex value \(*\text{this}\) and stores the result in \(*\text{this}\).

*Returns:* \(*\text{this}\).

```cpp
constexpr complex& operator/=(const T& rhs);
```

*Effects:* Divides the scalar value \( \text{rhs} \) into the complex value \(*\text{this}\) and stores the result in \(*\text{this}\).

*Returns:* \(*\text{this}\).

```cpp
template<class X> constexpr complex& operator=(const complex<X>& rhs);
```

*Effects:* Assigns the value \( \text{rhs}.\text{real}() \) to the real part and the value \( \text{rhs}.\text{imag}() \) to the imaginary part of the complex value \(*\text{this}\).

*Returns:* \(*\text{this}\).

```cpp
template<class X> constexpr complex& operator+=(const complex<X>& rhs);
```

*Effects:* Adds the complex value \( \text{rhs} \) to the complex value \(*\text{this}\) and stores the sum in \(*\text{this}\).

*Returns:* \(*\text{this}\).

```cpp
template<class X> constexpr complex& operator-=(const complex<X>& rhs);
```

*Effects:* Subtracts the complex value \( \text{rhs} \) from the complex value \(*\text{this}\) and stores the difference in \(*\text{this}\).
Returns: *this.

```cpp
template<class X> constexpr complex& operator*=(const complex<X>& rhs);
```

**Effects:** Multiplies the complex value `rhs` by the complex value `*this` and stores the product in `*this`.

**Returns:** *this.

```cpp
template<class X> constexpr complex& operator/=(const complex<X>& rhs);
```

**Effects:** Divides the complex value `rhs` into the complex value `*this` and stores the quotient in `*this`.

**Returns:** *this.

### 28.4.6 Non-member operations

```cpp
template<class T> constexpr complex<T> operator+(const complex<T>& lhs);
```

**Returns:** `complex<T>(lhs)`.

```cpp
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);
```

**Returns:** `complex<T>(lhs) += rhs`.

```cpp
template<class T> constexpr complex<T> operator-(const complex<T>& lhs);
```

**Returns:** `complex<T>(-lhs.real(), -lhs.imag())`.

```cpp
template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> constexpr complex<T> operator-(const T& lhs, const complex<T>& rhs);
```

**Returns:** `complex<T>(lhs) -= rhs`.

```cpp
template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> constexpr complex<T> operator*(const T& lhs, const complex<T>& rhs);
```

**Returns:** `complex<T>(lhs) *= rhs`.

```cpp
template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);
```

**Returns:** `lhs.real() == rhs.real() && lhs.imag() == rhs.imag()`.

**Remarks:** The imaginary part is assumed to be `T()`, or 0.0, for the `T` arguments.

```cpp
template<class T, class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);
```

**Preconditions:** The input values are convertible to `T`.

**Effects:** Extracts a complex number `x` of the form: `u, (u), or (u, v)`, where `u` is the real part and `v` is the imaginary part (31.7.5.3).

If bad input is encountered, calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure (31.5.4.4)`).

**Returns:** `is`.

**Remarks:** This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

```cpp
template<class T, class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);
```

**Effects:** Inserts the complex number `x` onto the stream `o` as if it were implemented as follows:
basic_ostringstream< charT, traits> s;
s.flags(o.flags());
s.imbue(o.getloc());
s.precision(o.precision());
s << '(' << x.real() << ',' << x.imag() << ')';
return o << s.str();

[Note 1: In a locale in which comma is used as a decimal point character, the use of comma as a field separator can be ambiguous. Inserting showpoint into the output stream forces all outputs to show an explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted unambiguously. — end note]

28.4.7 Value operations [complex.value.ops]

template<class T> constexpr T real(const complex<T>& x);
1 Returns: x.real().

template<class T> constexpr T imag(const complex<T>& x);
2 Returns: x.imag().

template<class T> constexpr T abs(const complex<T>& x);
3 Returns: The magnitude of x.

template<class T> constexpr T arg(const complex<T>& x);
4 Returns: The phase angle of x, or atan2(imag(x), real(x)).

template<class T> constexpr T norm(const complex<T>& x);
5 Returns: The squared magnitude of x.

template<class T> constexpr complex<T> conj(const complex<T>& x);
6 Returns: The complex conjugate of x.

template<class T> constexpr complex<T> proj(const complex<T>& x);
7 Returns: The projection of x onto the Riemann sphere.
8 Remarks: Behaves the same as the C function cproj. See also: ISO/IEC 9899:2018, 7.3.9.5

template<class T> constexpr complex<T> polar(const T& rho, const T& theta = T());
9 Preconditions: rho is non-negative and non-NaN. theta is finite.
10 Returns: The complex value corresponding to a complex number whose magnitude is rho and whose phase angle is theta.

28.4.8 Transcendentals [complex.transcendentals]

template<class T> constexpr complex<T> acos(const complex<T>& x);
1 Returns: The complex arc cosine of x.
2 Remarks: Behaves the same as the C function cacos. See also: ISO/IEC 9899:2018, 7.3.5.1

template<class T> constexpr complex<T> asin(const complex<T>& x);
3 Returns: The complex arc sine of x.
4 Remarks: Behaves the same as the C function casin. See also: ISO/IEC 9899:2018, 7.3.5.2

template<class T> constexpr complex<T> atan(const complex<T>& x);
5 Returns: The complex arc tangent of x.
6 Remarks: Behaves the same as the C function catan. See also: ISO/IEC 9899:2018, 7.3.5.3

template<class T> constexpr complex<T> acosh(const complex<T>& x);
7 Returns: The complex arc hyperbolic cosine of x.
8 Remarks: Behaves the same as the C function cacosh. See also: ISO/IEC 9899:2018, 7.3.6.1
template<class T> constexpr complex<T> asinh(const complex<T>& x);

Returns: The complex arc hyperbolic sine of \( x \).
Remarks: Behaves the same as the C function \texttt{casinh}.
See also: ISO/IEC 9899:2018, 7.3.6.2

template<class T> constexpr complex<T> atanh(const complex<T>& x);

Returns: The complex arc hyperbolic tangent of \( x \).
Remarks: Behaves the same as the C function \texttt{catanh}.
See also: ISO/IEC 9899:2018, 7.3.6.3

template<class T> constexpr complex<T> cos(const complex<T>& x);

Returns: The complex cosine of \( x \).

template<class T> constexpr complex<T> cosh(const complex<T>& x);

Returns: The complex hyperbolic cosine of \( x \).

template<class T> constexpr complex<T> exp(const complex<T>& x);

Returns: The complex base-\( e \) exponential of \( x \).

template<class T> constexpr complex<T> log(const complex<T>& x);

Returns: The complex natural (base-\( e \)) logarithm of \( x \). For all \( x \), \( \text{imag}(\log(x)) \) lies in the interval \([-\pi, \pi]\).

Note 1: The semantics of this function are intended to be the same in C++ as they are for \texttt{clog} in C. — end note

Remarks: The branch cuts are along the negative real axis.

template<class T> constexpr complex<T> log10(const complex<T>& x);

Returns: The complex common (base-10) logarithm of \( x \), defined as \( \log(x) / \log(10) \).

Remarks: The branch cuts are along the negative real axis.

template<class T> constexpr complex<T> pow(const complex<T>& x, const complex<T>& y);
template<class T> constexpr complex<T> pow(const complex<T>& x, const T& y);
template<class T> constexpr complex<T> pow(const T& x, const complex<T>& y);

Returns: The complex power of base \( x \) raised to the \( y \)th power, defined as \( \exp(y \times \log(x)) \). The value returned for \( \text{pow}(0, 0) \) is implementation-defined.

Remarks: The branch cuts are along the negative real axis.

template<class T> constexpr complex<T> sin(const complex<T>& x);

Returns: The complex sine of \( x \).

template<class T> constexpr complex<T> sinh(const complex<T>& x);

Returns: The complex hyperbolic sine of \( x \).

template<class T> constexpr complex<T> sqrt(const complex<T>& x);

Returns: The complex square root of \( x \), in the range of the right half-plane.

Note 2: The semantics of this function are intended to be the same in C++ as they are for \texttt{csqrt} in C. — end note

Remarks: The branch cuts are along the negative real axis.

template<class T> constexpr complex<T> tan(const complex<T>& x);

Returns: The complex tangent of \( x \).

template<class T> constexpr complex<T> tanh(const complex<T>& x);

Returns: The complex hyperbolic tangent of \( x \).

28.4.9 Tuple interface

```cpp
template<class T>
struct tuple_size<complex<T>> : integral_constant<size_t, 2> {};
```

§ 28.4.9
template<size_t I, class T>
struct tuple_element<I, complex<T>> {
    using type = T;
};

Mandates: I < 2 is true.

template<size_t I, class T>
constexpr T& get(complex<T>& z) noexcept;
template<size_t I, class T>
constexpr T&& get(complex<T>&& z) noexcept;
template<size_t I, class T>
constexpr const T& get(const complex<T>& z) noexcept;
template<size_t I, class T>
constexpr const T&& get(const complex<T>&& z) noexcept;

Mandates: I < 2 is true.

Returns: A reference to the real part of z if I == 0 is true, otherwise a reference to the imaginary part of z.

28.4.10 Additional overloads
[cmplx.over]

The following function templates have additional constexpr overloads:

arg norm
conj proj
imag real

The additional constexpr overloads are sufficient to ensure:

(2.1) — If the argument has a floating-point type T, then it is effectively cast to complex<T>.

(2.2) — Otherwise, if the argument has integer type, then it is effectively cast to complex<double>.

Function template pow has additional constexpr overloads sufficient to ensure, for a call with one argument of type complex<T1> and the other argument of type T2 or complex<T2>, both arguments are effectively cast to complex<common_type_t<T1, T2>>. If common_type_t<T1, T2> is not well-formed, then the program is ill-formed.

28.4.11 Suffixes for complex number literals
[complex.literals]

This subclause describes literal suffixes for constructing complex number literals. The suffixes i, il, and if create complex numbers of the types complex<double>, complex<long double>, and complex<float> respectively, with their imaginary part denoted by the given literal number and the real part being zero.

constexpr complex<long double> operator"il(long double d);
constexpr complex<long double> operator"il(unsigned long long d);

Returns: complex<long double>{0.0L, static_cast<long double>(d)}.

constexpr complex<double> operator"i(long double d);
constexpr complex<double> operator"i(unsigned long long d);

Returns: complex<double>{0.0, static_cast<double>(d)}.

constexpr complex<float> operator"if(long double d);
constexpr complex<float> operator"if(unsigned long long d);

Returns: complex<float>{0.0f, static_cast<float>(d)}.

28.5 Random number generation
[rand]

28.5.1 General
[rand.general]

Subclause 28.5 defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that meet the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated.
Each of the entities specified in §28.5 has an associated arithmetic type (6.8.2) identified as `result_type`. With T as the `result_type` thus associated with such an entity, that entity is characterized:

(3.1) — as `boolean` or equivalently as `boolean-valued`, if `T` is `bool`;
(3.2) — otherwise as `integral` or equivalently as `integer-valued`, if `numeric_limits<T>::is_integer` is `true`;
(3.3) — otherwise as `floating-point` or equivalently as `real-valued`.

If integer-valued, an entity may optionally be further characterized as `signed` or `unsigned`, according to `numeric_limits<T>::is_signed`.

4 Unless otherwise specified, all descriptions of calculations in §28.5 use mathematical real numbers.

5 Throughout §28.5, the operators `bitand`, `bitor`, and `xor` denote the respective conventional bitwise operations. Further:

(5.1) — the operator `rshift` denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and
(5.2) — the operator `lshift` denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo $2^w$.

### 28.5.2 Header `<random>` synopsis

```cpp
#include <initializer_list>    // see 17.10.2

namespace std {
    // §28.5.3.3, uniform random bit generator requirements
    template<class G>
    concept uniform_random_bit_generator = see below;

template<class RealType = double>
   class normal_distribution;
28.5.3 Requirements

28.5.3.1 General requirements

1 Throughout this subclause 28.5, the effect of instantiating a template:

   (1.1) that has a template type parameter named \texttt{Sseq} is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of seed sequence (28.5.3.2).

   (1.2) that has a template type parameter named \texttt{URBG} is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of uniform random bit generator (28.5.3.3).

   (1.3) that has a template type parameter named \texttt{Engine} is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of random number engine (28.5.3.4).

   (1.4) that has a template type parameter named \texttt{RealType} is undefined unless the corresponding template argument is cv-unqualified and is one of \texttt{float}, \texttt{double}, or \texttt{long double}.

   (1.5) that has a template type parameter named \texttt{IntType} is undefined unless the corresponding template argument is cv-unqualified and is one of \texttt{short}, \texttt{int}, \texttt{long}, \texttt{long long}, \texttt{unsigned short}, \texttt{unsigned int}, \texttt{unsigned long}, or \texttt{unsigned long long}.

   (1.6) that has a template type parameter named \texttt{UIntType} is undefined unless the corresponding template argument is cv-unqualified and is one of \texttt{unsigned short}, \texttt{unsigned int}, \texttt{unsigned long}, or \texttt{unsigned long long}.

2 Throughout this subclause 28.5, phrases of the form “\texttt{x} is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “\texttt{x} is a value of a type meeting the requirements of the specified iterator type”.

3 Throughout this subclause 28.5, any constructor that can be called with a single argument and that meets a requirement specified in this subclause shall be declared \texttt{explicit}. 

\[ § \text{28.5.3.1} \]
28.5.3.2 Seed sequence requirements

A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values \(0 \leq i < 2^{32}\), based on the consumed data.

[Note 1: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note]

A class \(S\) meets the requirements of a seed sequence if the expressions shown in Table 95 are valid and have the indicated semantics, and if \(S\) also meets all other requirements of this subclause 28.5.3.2. In that Table and throughout this subclause:

- \(T\) is the type named by \(S\)'s associated \texttt{result_type};
- \(q\) is a value of type \(S\) and \(r\) is a value of type \(S\) or \texttt{const S};
- \(ib\) and \(ie\) are input iterators with an unsigned integer \texttt{value_type} of at least 32 bits;
- \(rb\) and \(re\) are mutable random access iterators with an unsigned integer \texttt{value_type} of at least 32 bits;
- \(ob\) is an output iterator; and
- \(il\) is a value of type \texttt{initializer_list<T>}.

</tr>
</tbody>
</table>

28.5.3.3 Uniform random bit generator requirements

A uniform random bit generator \(g\) of type \(G\) is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned.
[Note 1: The degree to which g’s results approximate the ideal is often determined statistically. — end note]

```cpp
template<class G>
concept uniform_random_bit_generator =
  invocable<G&> && unsigned_integral<invoke_result_t<G&>> &&
  requires {
    { G::min() } -> same_as<invoke_result_t<G&>>;
    { G::max() } -> same_as<invoke_result_t<G&>>;
    requires bool_constant<(G::min() < G::max())>::value;
  };
```

2 Let g be an object of type G. G models **uniform_random_bit_generator** only if

1. \( G::\text{min()}\) <= \( g() \),
2. \( g() \) <= \( G::\text{max()} \), and
3. \( g() \) has amortized constant complexity.

3 A class G meets the **uniform random bit generator** requirements if G models **uniform_random_bit_generator**, `invoke_result_t<G&>` is an unsigned integer type (6.8.2), and G provides a nested **typedef-name result_type** that denotes the same type as `invoke_result_t<G&>`.

### 28.5.3.4 Random number engine requirements

1 A **random number engine** (commonly shortened to **engine**) e of type E is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

2 At any given time, e has a state \( e_i \) for some integer \( i \geq 0 \). Upon construction, e has an initial state \( e_0 \). An engine’s state may be established via a constructor, a **seed** function, assignment, or a suitable **operator>>**.

3 E’s specification shall define:

   1. the size of E’s state in multiples of the size of **result_type**, given as an integral constant expression;
   2. the **transition algorithm** TA by which e’s state \( e_i \) is advanced to its successor state \( e_{i+1} \); and
   3. the **generation algorithm** GA by which an engine’s state is mapped to a value of type **result_type**.

4 A class E that meets the requirements of a uniform random bit generator (28.5.3.3) also meets the requirements of a **random number engine** if the expressions shown in Table 96 are valid and have the indicated semantics, and if E also meets all other requirements of this subclause 28.5.3.4. In that Table and throughout this subclause:

   1. T is the type named by E’s associated **result_type**;
   2. e is a value of E, v is an lvalue of E, x and y are (possibly const) values of E;
   3. s is a value of T;
   4. q is an lvalue meeting the requirements of a seed sequence (28.5.3.2);
   5. z is a value of type **unsigned long long**;
   6. os is an lvalue of the type of some class template specialization **basic_ostream<charT, traits>**; and
   7. is is an lvalue of the type of some class template specialization **basic_istream<charT, traits>**;

where **charT** and **traits** are constrained according to Clause 23 and Clause 31.

</tr>
</tbody>
</table>

\textsuperscript{224} This constructor (as well as the subsequent corresponding seed() function) can be particularly useful to applications requiring a large number of independent random sequences.

\textsuperscript{225} This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes z consecutive calls e().
<table>

<td>( O(\text{size of state}) )</td>
</tr>
</tbody>
</table>

5 E shall meet the `Cpp17CopyConstructible (Table 32)` and `Cpp17CopyAssignable (Table 34)` requirements. These operations shall each be of complexity no worse than \( O(\text{size of state}) \).

28.5.3.5 Random number engine adaptor requirements

1 A random number engine adaptor (commonly shortened to adaptor) `a` of type `A` is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine `b` of type `B` adapted in this way is termed a base engine in this context. The expression `a.base()` shall be valid and shall return a const reference to `a`'s base engine.

2 The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

3 \[ A::A(); \]

   \textbf{Effects}: The base engine is initialized as if by its default constructor.

4 \[ \text{bool operator==}(\text{const } A & a1, \text{const } A & a2); \]

   \textbf{Returns}: `true` if `a1`'s base engine is equal to `a2`'s base engine. Otherwise returns `false`.

5 \[ A::A(\text{result_type } s); \]

   \textbf{Effects}: The base engine is initialized with `s`.

6 \[ \text{template<}\!\!\text{class Seq} \!\!\!\text{>} A::A(Seq & q); \]

   \textbf{Effects}: The base engine is initialized with `q`.

7 \[ \text{void seed();} \]

   \textbf{Effects}: With `b` as the base engine, invokes `b.seed()`.

§ 28.5.3.5 1445
void seed(result_type s);

Effects: With b as the base engine, invokes b.seed(s).

template<class Sseq> void seed(Sseq& q);

Effects: With b as the base engine, invokes b.seed(q).

A shall also meet the following additional requirements:

1. The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.
2. The state of A shall include the state of its base engine. The size of A’s state shall be no less than the size of the base engine.
3. Copying A’s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of A.
4. The textual representation of A shall include the textual representation of its base engine.

28.5.3.6 Random number distribution requirements

A random number distribution (commonly shortened to distribution) d of type D is a function object returning values that are distributed according to an associated mathematical probability density function p(z) or according to an associated discrete probability function P(zᵢ). A distribution’s specification identifies its associated probability function p(z) or P(zᵢ).

An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, p(z | a, b) or P(zᵢ | a, b), to name specific parameters, or by writing, for example, p(z | {p}) or P(zᵢ | {p}), to denote a distribution’s parameters p taken as a whole.

A class D meets the requirements of a random number distribution if the expressions shown in Table 97 are valid and have the indicated semantics, and if D and its associated types also meet all other requirements of this subclause 28.5.3.6. In that Table and throughout this subclause,

- T is the type named by D’s associated result_type;
- P is the type named by D’s associated param_type;
- d is a value of D, and x and y are (possibly const) values of D’s;
- glb and lub are values of T respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by d’s operator(), as determined by the current values of d’s parameters;
- p is a (possibly const) value of P;
- g, g1, and g2 are lvalues of a type meeting the requirements of a uniform random bit generator (28.5.3.3);
- os is an lvalue of the type of some class template specialization basic_ostream<charT, traits>; and
- is is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 23 and Clause 31.

<tr>
<td>x == y</td>
<td>bool</td>
<td>This operator is an equivalence relation. Returns true if x.param() == y.param() and S_1 = S_2, where S_1 and S_2 are the infinite sequences of values that would be generated, respectively, by repeated future calls to x(g1) and y(g2) whenever g1 == g2. Otherwise returns false.</td>
<td>constant</td>
</tr>
<tr>
<td>x != y</td>
<td>bool</td>
<td>!(x == y).</td>
<td>same as x == y.</td>
</tr>
<tr>
<td>os &lt;&lt; x</td>
<td>reference to the type of os</td>
<td>Writes to os a textual representation for the parameters and the additional internal data of x. Postconditions: The os.fmtflags and fill character are unchanged.</td>
<td></td>
</tr>
</tbody>
</table>

§ 28.5.3.6
<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>is &gt;&gt; d</code></td>
<td>reference to the type of <code>is</code></td>
<td>Restores from <code>is</code> the parameters and additional internal data of the lvalue <code>d</code>. If bad input is encountered, ensures that <code>d</code> is unchanged by the operation and calls <code>is.setstate(ios_base::failbit)</code> (which may throw <code>ios_base::failure</code> (31.5.4.4)).</td>
<td></td>
</tr>
</tbody>
</table>

**Preconditions:** `is` provides a textual representation that was previously written using an `os` whose imbued locale and whose type’s template specialization arguments `charT` and `traits` were the same as those of `is`.  
**Postconditions:** The `is.fmtflags` are unchanged.

---

4 D shall meet the *Cpp17CopyConstructible* (Table 32) and *Cpp17CopyAssignable* (Table 34) requirements.

5 The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of D between any of the invocations of `d(g)`.

6 If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.

7 It is unspecified whether `D::param_type` is declared as a (nested) `class` or via a `typedef`. In this subclause 28.5, declarations of `D::param_type` are in the form of `typedefs` for convenience of exposition only.

8 P shall meet the *Cpp17CopyConstructible* (Table 32), *Cpp17CopyAssignable* (Table 34), and *Cpp17Equality-Comparable* (Table 28) requirements.

9 For each of the constructors of D taking arguments corresponding to parameters of the distribution, P shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of D that return values corresponding to parameters of the distribution, P shall have a corresponding member function with the identical name, type, and semantics.

10 P shall have a declaration of the form

```cpp
using distribution_type = D;
```

### Rand.eng

#### Rand.eng.general

1 Each type instantiated from a class template specified in 28.5.4 meets the requirements of a random number engine (28.5.3.4) type.

2 Except where specified otherwise, the complexity of each function specified in 28.5.4 is constant.

3 Except where specified otherwise, no function described in 28.5.4 throws an exception.

4 Every function described in 28.5.4 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of `q.generate` throws.

5 Descriptions are provided in 28.5.4 only for engine operations that are not described in 28.5.3.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.
Each template specified in 28.5.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

For every random number engine and for every random number engine adaptor \( X \) defined in 28.5.4 and in 28.5.5:

(7.1) — if the constructor

\[
\text{template<class Sseq> explicit } X(Sseq& q);
\]

is called with a type \( Sseq \) that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) — if the member function

\[
\text{template<class Sseq> void } \text{seed}(Sseq& q);
\]

is called with a type \( Sseq \) that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to \( X::\text{result}\_\text{type} \).

28.5.4.2 Class template \texttt{linear\_congruential\_engine} \[\text{rand.\textsc{eng.lcong}}\]

A \texttt{linear\_congruential\_engine} random number engine produces unsigned integer random numbers. The state \( x_i \) of a \texttt{linear\_congruential\_engine} object \( x \) is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form \( TA(x_i) = (a \cdot x_i + c) \mod m \); the generation algorithm is \( GA(x_i) = x_{i+1} \).

namespace std {
    template<class UIntType, UIntType a, UIntType c, UIntType m>
    class linear_congruential_engine {
        public:
            // types
            using result_type = UIntType;

            // engine characteristics
            static constexpr result_type multiplier = a;
            static constexpr result_type increment = c;
            static constexpr result_type modulus = m;
            static constexpr result_type min() { return c == 0u ? 1u: 0u; }
            static constexpr result_type max() { return m - 1u; }
            static constexpr result_type default_seed = 1u;

            // constructors and seeding functions
            linear_congruential_engine() : linear_congruential_engine(default_seed) {};
            explicit linear_congruential_engine(result_type s);
            template<class Sseq> explicit linear_congruential_engine(Sseq& q);
            void seed(result_type s = default_seed);
            template<class Sseq> void seed(Sseq& q);

            // equality operators
            friend bool operator==(const linear_congruential_engine& x,
                                  const linear_congruential_engine& y);

            // generating functions
            result_type operator()();
            void discard(unsigned long long z);

            // inserters and extractors
            template<class charT, class traits>
                friend basic_ostream<charT, traits>&
                    operator<<(basic_ostream<charT, traits>& os, const linear_congruential_engine& x);
            template<class charT, class traits>
                friend basic_istream<charT, traits>&
                    operator>>(basic_istream<charT, traits>& is, linear_congruential_engine& x);
    }
}
Let (3.4) with $\alpha$ a twist value.

Effects: If $c \mod m$ is 0 and $s \mod m$ is 0, sets the engine’s state to 1, otherwise sets the engine’s state to $s \mod m$.

4 The textual representation consists of the value of $x_i$.

explicit linear_congruential_engine(result_type s);

Effects: If $c \mod m$ is 0 and $s \mod m$ is 0, sets the engine’s state to 1, otherwise sets the engine’s state to $s \mod m$.

template<class Sseq> explicit linear_congruential_engine(Sseq& q);

Effects: With $k = \left\lceil \log_2 m \right\rceil$ and $a$ an array (or equivalent) of length $k + 3$, invokes $q.generate(a + 0, a + k + 3)$ and then computes $S = \left( \sum_{j=0}^{k-1} a_j \cdot 2^{32j} \right) \mod m$. If $c \mod m$ is 0 and $S$ is 0, sets the engine’s state to 1, else sets the engine’s state to $S$.

28.5.4.3 Class template mersenne_twister_engine

A mersenne_twister_engine random number engine produces unsigned integer random numbers in the closed interval $[0, 2^w - 1]$. The state $x_i$ of a mersenne_twister_engine object $x$ is of size $n$ and consists of a sequence $X$ of $n$ values of the type delivered by $x$; all subscripts applied to $X$ are to be taken modulo $n$.

The transition algorithm employs a twisted generalized feedback shift register defined by shift values $n$ and $m$, a twist value $r$, and a conditional xor-mask $a$. To improve the uniformity of the result, the bits of the raw shift register are additionally tempered (i.e., scrambled) according to a bit-scrambling matrix defined by values $u, d, s, b, t, c$, and $\ell$.

The state transition is performed as follows:

(2.1) Concatenate the upper $w - r$ bits of $X_{i - n}$ with the lower $r$ bits of $X_{i + 1 - n}$ to obtain an unsigned integer value $Y$.

(2.2) With $\alpha = a \cdot (Y \text{ bitand } 1)$, set $X_i$ to $X_{i + m - n} \text{xor} (Y \text{ rshift } 1) \text{xor} \alpha$.

The sequence $X$ is initialized with the help of an initialization multiplier $f$.

The generation algorithm determines the unsigned integer values $z_1, z_2, z_3, z_4$ as follows, then delivers $z_4$ as its result:

(3.1) Let $z_1 = X_i \text{xor} ((X_i \text{ rshift } u) \text{ bitand } d)$.

(3.2) Let $z_2 = z_1 \text{xor} ((z_1 \text{ lshift } w) \text{ bitand } b)$.

(3.3) Let $z_3 = z_2 \text{xor} ((z_2 \text{ lshift } t) \text{ bitand } c)$.

(3.4) Let $z_4 = z_3 \text{xor} (z_3 \text{ rshift } \ell)$.

namespace std {

template<

class mersenne_twister_engine {

public:

// types

using result_type = UIntType;

// engine characteristics

static constexpr size_t word_size = w;
static constexpr size_t state_size = n;
static constexpr size_t shift_size = m;
static constexpr size_t mask_bits = r;

226) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.
static constexpr UIntType xor_mask = a;
static constexpr size_t tempering_u = u;
static constexpr UIntType tempering_d = d;
static constexpr size_t tempering_s = s;
static constexpr UIntType tempering_b = b;

static constexpr UIntType tempering_c = c;
static constexpr size_t tempering_l = l;
static constexpr UIntType initialization_multiplier = f;
static constexpr result_type min() { return 0; }
static constexpr result_type max() { return 2w - 1; }
static constexpr result_type default_seed = 5489u;

// constructors and seeding functions
mersenne_twister_engine() : mersenne_twister_engine(default_seed) {}
explicit mersenne_twister_engine(result_type value);
template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
void seed(result_type value = default_seed);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const mersenne_twister_engine& x, const mersenne_twister_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const mersenne_twister_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, mersenne_twister_engine& x);

4 The following relations shall hold: 0 < m, m <= n, 2u < w, r <= w, u <= w, s <= w, t <= w, l <= w, w <= numeric_limits<UIntType>::digits, a <= (1u<<w) - 1u, b <= (1u<<w) - 1u, c <= (1u<<w) - 1u, d <= (1u<<w) - 1u, and f <= (1u<<w) - 1u.
5 The textual representation of \( x_i \) consists of the values of \( X_{i-n}, \ldots, X_{i-1} \), in that order.
6 Effects: Sets \( X_{-n} \) to value \( \mod 2^w \). Then, iteratively for \( i = 1-n, \ldots, -1 \), sets \( X_i \) to
\[
[f \cdot (X_{i-1} \text{xor} (X_{i-1} \text{rshift} (w - 2))) + i \text{ mod } n] \mod 2^w.
\]
7 Complexity: \( O(n) \).

template<class Sseq> explicit mersenne_twister_engine(Sseq& q);

Effects: With \( k = \lceil w/32 \rceil \) and \( a \) an array (or equivalent) of length \( n \cdot k \), invokes \( q \).generate(\( a + 0, a + n \cdot k \)) and then, iteratively for \( i = -n, \ldots, -1 \), sets \( X_i \) to \( \left( \sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j} \right) \) \mod 2^w. Finally, if the most significant \( w - r \) bits of \( X_{-n} \) are zero, and if each of the other resulting \( X_i \) is 0, changes \( X_{-n} \) to \( 2^w - 1 \).

28.5.4.4 Class template subtract_with_carry_engine [rand.eng.sub]

A subtract_with_carry_engine random number engine produces unsigned integer random numbers.

The state \( x_i \) of a subtract_with_carry_engine object \( x \) is of size \( O(r) \), and consists of a sequence \( X \) of \( r \) integer values \( 0 \leq X_i < m = 2^r \); all subscripts applied to \( X \) are to be taken modulo \( r \). The state \( x_i \) additionally consists of an integer \( c \) (known as the carry) whose value is either 0 or 1.

The state transition is performed as follows:

\[ x_{i+1} = (x_i \oplus c) \cdot (2^{w-r} + 1) \mod m \]
\[ c_{i+1} = (x_i \cdot 2^r \mod m - x_{i+1}) / m \]

where \( \oplus \) denotes bitwise exclusive or, and \( \cdot \) denotes integer multiplication.
Let \( Y = X_{i-s} - X_{i-r} - c \).

Set \( X_i \) to \( y = Y \mod m \). Set \( c \) to 1 if \( Y < 0 \), otherwise set \( c \) to 0.

[Note 1: This algorithm corresponds to a modular linear function of the form \( TA(x_i) = (a \cdot x_i) \mod b \), where \( b \) is of the form \( m^r - m^s + 1 \) and \( a = b - (b - 1)/m \). — end note]

The generation algorithm is given by \( GA(x_i) = y \), where \( y \) is the value produced as a result of advancing the engine’s state as described above.

```cpp
namespace std {
    template<class UIntType, size_t w, size_t s, size_t r>
    class subtract_with_carry_engine {
    public:
        // types
        using result_type = UIntType;
        // engine characteristics
        static constexpr size_t word_size = w;
        static constexpr size_t short_lag = s;
        static constexpr size_t long_lag = r;
        static constexpr result_type min() { return 0; }
        static constexpr result_type max() { return m - 1; }
        static constexpr uint_least32_t default_seed = 19780503u;
        // constructors and seeding functions
        subtract_with_carry_engine() : subtract_with_carry_engine(0u) {};
        explicit subtract_with_carry_engine(result_type value);
        template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
        void seed(result_type value = 0u);
        template<class Sseq> void seed(Sseq& q);
        // equality operators
        friend bool operator==(const subtract_with_carry_engine& x, const subtract_with_carry_engine& y);
        // generating functions
        result_type operator()();
        void discard(unsigned long long z);
        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const subtract_with_carry_engine& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, subtract_with_carry_engine& x);
    };
}
```

The following relations shall hold: \( 0u < s, s < r, 0 < w \), and \( w \leq \text{numeric_limits}<\text{UIntType}>::\text{digits} \).

The textual representation consists of the values of \( X_{i-r}, \ldots, X_{i-1} \), in that order, followed by \( c \).

```cpp
explicit subtract_with_carry_engine(result_type value);
```

**Effects:** Sets the values of \( X_{i-r}, \ldots, X_{i-1} \), in that order, as specified below. If \( X_{i-1} \) is then 0, sets \( c \) to 1; otherwise sets \( c \) to 0.

To set the values \( X_k \), first construct \( e \), a `linear_congruential_engine` object, as if by the following definition:

```cpp
linear_congruential_engine<uint_least32_t, 40014u, 0u, 2147483563u> e(value == 0u ? default_seed : value);
```

Then, to set each \( X_k \), obtain new values \( z_0, \ldots, z_{n-1} \) from \( n = \lceil w/32 \rceil \) successive invocations of \( e \). Set \( X_k \) to \( \left( \sum_{j=0}^{n-1} z_j \cdot 2^{32j} \right) \mod m \).

**Complexity:** Exactly \( n \cdot r \) invocations of \( e \).
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);

Effects: With \( k = \lceil w/32 \rceil \) and \( a \) an array (or equivalent) of length \( r \cdot k \), invokes \( q.\text{generate}(a + 0, a + r \cdot k) \) and then, iteratively for \( i = -r, \ldots, -1 \), sets \( X_i \) to \( \left( \sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j} \right) \mod m \). If \( X_{-1} \) is then 0, sets \( c \) to 1; otherwise sets \( c \) to 0.

28.5.5 Random number engine adaptor class templates

28.5.5.1 In general

Each type instantiated from a class template specified in this subclause 28.5.5 meets the requirements of a random number engine adaptor (28.5.3.5) type.

Except where specified otherwise, the complexity of each function specified in this subclause 28.5.5 is constant.

Except where specified otherwise, no function described in this subclause 28.5.5 throws an exception.

Every function described in this subclause 28.5.5 that has a function parameter \( q \) of type \( Sseq \& \) for a template type parameter named \( Sseq \) that is different from type \( seed\_seq \) throws what and when the invocation of \( q.\text{generate} \) throws.

Descriptions are provided in this subclause 28.5.5 only for adaptor operations that are not described in subclause 28.5.3.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in this subclause 28.5.5 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

28.5.5.2 Class template discard_block_engine

A \( \text{discard\_block\_engine} \) random number engine adaptor produces random numbers selected from those produced by some base engine \( e \). The state \( x_i \) of a \( \text{discard\_block\_engine} \) engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \) and an additional integer \( n \). The size of the state is the size of \( e \)'s state plus 1.

The transition algorithm discards all but \( r > 0 \) values from each block of \( p \geq r \) values delivered by \( e \). The state transition is performed as follows: If \( n \geq r \), advance the state of \( e \) from \( e_i \) to \( e_i + p - r \) and set \( n \) to 0. In any case, then increment \( n \) and advance \( e \)'s then-current state \( e_j \) to \( e_{j+1} \).

The generation algorithm yields the value returned by the last invocation of \( e() \) while advancing \( e \)'s state as described above.

namespace std {
    template<class Engine, size_t p, size_t r>
    class discard_block_engine {
    public:
        // types
        using result_type = typename Engine::result_type;

        // engine characteristics
        static constexpr size_t block_size = p;
        static constexpr size_t used_block = r;
        static constexpr result_type min() { return Engine::min(); }
        static constexpr result_type max() { return Engine::max(); }

        // constructors and seeding functions
        discard_block_engine();
        explicit discard_block_engine(const Engine& e);
        explicit discard_block_engine(Engine&& e);
        explicit discard_block_engine(result_type s);
        template<class Sseq> explicit discard_block_engine(Sseq& q);
        void seed();
        void seed(result_type s);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const discard_block_engine& x, const discard_block_engine& y);
    }
4 The following relations shall hold: \(0 < r\) and \(r \leq p\).

5 The textual representation consists of the textual representation of \(e\) followed by the value of \(n\).

6 In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor sets \(n\) to 0.

28.5.5.3 Class template independent_bits_engine

An independent_bits_engine random number engine adaptor combines random numbers that are produced by some base engine \(e\), so as to produce random numbers with a specified number of bits \(w\). The state \(x_i\) of an independent_bits_engine engine adaptor object \(x\) consists of the state \(e_i\) of its base engine \(e\); the size of the state is the size of \(e\)'s state.

2 The transition and generation algorithms are described in terms of the following integral constants:

1. Let \(R = e_{\text{max}}() - e_{\text{min}}() + 1\) and \(m = \lceil \log_2 R \rceil\).
2. With \(n\) as determined below, let \(w_0 = \lfloor w/n \rfloor\), \(n_0 = n - w \mod n\), \(y_0 = 2^{w_0} \lfloor R / 2^{w_0} \rfloor\), and \(y_1 = 2^{w_0+1} \lfloor R / 2^{w_0+1} \rfloor\).
3. Let \(n = \lceil w / m \rceil\) if and only if the relation \(R - y_0 \leq \lfloor y_0 / n \rfloor\) holds as a result. Otherwise let \(n = 1 + \lceil w / m \rceil\).
4. The transition algorithm is carried out by invoking \(e()\) as often as needed to obtain \(n_0\) values less than \(y_0 + e_{\text{min}}()\) and \(n - n_0\) values less than \(y_1 + e_{\text{min}}()\).

3 The generation algorithm uses the values produced while advancing the state as described above to yield a quantity \(S\) obtained as if by the following algorithm:

\[
S = 0; \\
\text{for (} k = 0; \ k \neq n_0; \ k += 1 \text{) \{} \\
\quad \text{do } u = e() - e_{\text{min}}(); \text{ while } (u \geq y_0); \\
\quad S = 2^{w_0} \cdot S + u \mod 2^{w_0}; \\
\text{\}} \\
\text{for (} k = n_0; \ k \neq n; \ k += 1 \text{) \{} \\
\quad \text{do } u = e() - e_{\text{min}}(); \text{ while } (u \geq y_1); \\
\quad S = 2^{w_0+1} \cdot S + u \mod 2^{w_0+1}; \\
\text{\}}
\]
static constexpr result_type max() { return 2\(^w\) \(- 1\); }

// constructors and seeding functions
independent_bits_engine();
explicit independent_bits_engine(const Engine& e);
explicit independent_bits_engine(Engine&& e);
explicit independent_bits_engine(result_type s);
template<class Sseq> explicit independent_bits_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const independent_bits_engine& x, const independent_bits_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const independent_bits_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, independent_bits_engine& x);

private:
  Engine e;  // exposition only
};

The following relations shall hold: 0 < w and w \leq\text{numeric\_limits\<result\_type\>:\:digits}.
The textual representation consists of the textual representation of e.

28.5.5.4 Class template shuffle_order_engine

A \textit{shuffle\_order\_engine} random number engine adaptor produces the same random numbers that are
produced by some base engine \texttt{e}, but delivers them in a different sequence. The state \texttt{x} of a \texttt{shuffle\_order\_engine}
engine adaptor object \texttt{x} consists of the state \texttt{e} of its base engine \texttt{e}, an additional value \texttt{Y} of
the type delivered by \texttt{e}, and an additional sequence \texttt{V} of \texttt{k} values also of the type delivered by \texttt{e}. The size
of the state is the size of \texttt{e}'s state plus \texttt{k} + 1.

The transition algorithm permutes the values produced by \texttt{e}. The state transition is performed as follows:

\begin{enumerate}
\item[(2.1)] Calculate an integer \(j = \left\lfloor \frac{k \cdot (Y - e_{\text{min}})}{e_{\text{max}} - e_{\text{min}} + 1} \right\rfloor\).
\item[(2.2)] Set \texttt{Y} to \texttt{V}_j and then set \texttt{V}_j to \texttt{e}().
\end{enumerate}

The generation algorithm yields the last value of \texttt{Y} produced while advancing \texttt{e}'s state as described above.

namespace std {
  template<class Engine, size_t k>
  class shuffle_order_engine {
    public:
      using result_type = typename Engine::result_type;

      // engine characteristics
      static constexpr size_t table_size = k;
      static constexpr result_type min() { return Engine::min(); }
      static constexpr result_type max() { return Engine::max(); }
  }
// constructors and seeding functions
shuffle_order_engine();
explicit shuffle_order_engine(const Engine& e);
explicit shuffle_order_engine(Engine&& e);
explicit shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const shuffle_order_engine& x, const shuffle_order_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
cost Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>& 
operator<<(basic_ostream<charT, traits>& os, const shuffle_order_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, shuffle_order_engine& x);

private:
Engine e; // exposition only
result_type V[k]; // exposition only
result_type Y; // exposition only
};

4 The following relation shall hold: 0 < k.
5 The textual representation consists of the textual representation of e, followed by the k values of V, followed by the value of Y.
6 In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor initializes V[0],...,V[k-1] and Y, in that order, with values returned by successive invocations of e().

28.5.6 Engines and engine adaptors with predefined parameters [rand.predef]

using minstd_rand0 =
linear_congruential_engine<uint_fast32_t, 16'807, 0, 2'147'483'647>;

1 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 produces the value 1043618065.

using minstd_rand =
linear_congruential_engine<uint_fast32_t, 48'271, 0, 2'147'483'647>;

2 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand produces the value 399268537.

using mt19937 =
mersenne_twister_engine<uint_fast32_t, 32, 624, 397, 31,
0x9908'b0df, 11, 0xffff'ffff, 7, 0x9d2c'5680, 15, 0xefc6'0000, 18, 1'812'433'253>;

3 Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937 produces the value 4123659995.
using mt19937_64 =
    mersenne_twister_engine<uint_fast64_t, 64, 312, 156, 31,
    0xb502'6f5a'a966'19e9, 29, 0x5555'5555'5555'5555, 17,
    0x71d6'7fff'eda6'0000, 37, 0xff7'eee0'0000'0000, 43, 6'364'136'223'846'793'005>;

4   Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937_-
64 produces the value 9981545732273789042.

using ranlux24_base =
    subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>;

5   Required behavior: The 10000th consecutive invocation of a default-constructed object of type ran-
lux24_base produces the value 7937952.

using ranlux48_base =
    subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>;

6   Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48_base
produces the value 61839128582725.

using ranlux24 = discard_block_engine<ranlux24_base, 223, 23>;

7   Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24
produces the value 9901578.

using ranlux48 = discard_block_engine<ranlux48_base, 389, 11>;

8   Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48
produces the value 249142670248501.

using knuth_b = shuffle_order_engine<minstd_rand0,256>;

9   Required behavior: The 10000th consecutive invocation of a default-constructed object of type knuth_b
produces the value 1112339016.

using default_random_engine = implementation-defined;

Remarks: The choice of engine type named by this typedef is implementation-defined.

[Note 1: The implementation can select this type on the basis of performance, size, quality, or any combination
of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or
lightweight use. Because different implementations can select different underlying engine types, code that uses
this typedef need not generate identical sequences across implementations. — end note]

28.5.7   Class random_device [rand.device]

1   A random_device uniform random bit generator produces nondeterministic random numbers.

2   If implementation limitations prevent generating nondeterministic random numbers, the implementation may
employ a random number engine.

namespace std {
    class random_device {
        public:
            // types
            using result_type = unsigned int;

            // generator characteristics
            static constexpr result_type min() { return numeric_limits<result_type>::min(); }  
            static constexpr result_type max() { return numeric_limits<result_type>::max(); }

            // constructors
            random_device() : random_device(implementation-defined) {}  
            explicit random_device(const string& token);

            // generating functions
            result_type operator()();

            // property functions
            double entropy() const noexcept;
        }
// no copy functions
random_device(const random_device&) = delete;
void operator=(const random_device&) = delete;
};
}

explicit random_device(const string& token);

3 Throws: A value of an implementation-defined type derived from exception if the random_device cannot be initialized.

4 Remarks: The semantics of the token parameter and the token value used by the default constructor are implementation-defined.\(^227\)

double entropy() const noexcept;

5 Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate\(^228\) for the random numbers returned by operator(), in the range min() to log_2(max() + 1).

result_type operator()();

6 Returns: A nondeterministic random value, uniformly distributed between min() and max() (inclusive). It is implementation-defined how these values are generated.

7 Throws: A value of an implementation-defined type derived from exception if a random number cannot be obtained.

28.5.8 Utilities [rand.util]

28.5.8.1 Class seed_seq [rand.util.seedseq]

namespace std {
    class seed_seq {
    public:
        // types
        using result_type = uint_least32_t;

        // constructors
        seed_seq() noexcept;
        template<class T>
            seed_seq(initializer_list<T> il);
        template<class InputIterator>
            seed_seq(InputIterator begin, InputIterator end);

        // generating functions
        template<class RandomAccessIterator>
            void generate(RandomAccessIterator begin, RandomAccessIterator end);

        // property functions
        size_t size() const noexcept;
        template<class OutputIterator>
            void param(OutputIterator dest) const;

        // no copy functions
        seed_seq(const seed_seq&) = delete;
        void operator=(const seed_seq&) = delete;

    private:
        vector<result_type> v;  // exposition only
    };
}

\(^227\) The parameter is intended to allow an implementation to differentiate between different sources of randomness.

\(^228\) If a device has \(n\) states whose respective probabilities are \(P_0, \ldots, P_{n-1}\), the device entropy \(S\) is defined as

\[
S = -\sum_{i=0}^{n-1} P_i \cdot \log P_i.
\]
seed_seq() noexcept;

1
Postconditions: v.empty() is true.

template<class T>
seed_seq(initializer_list<T> il);

2
Constraints: T is an integer type.

Effects: Same as seed_seq(il.begin(), il.end()).

template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);

3
Mandates: iterator_traits<InputIterator>::value_type is an integer type.

4
Preconditions: InputIterator meets the Cpp17InputIterator requirements (25.3.5.3).

5
Effects: Initializes v by the following algorithm:

6
for (InputIterator s = begin; s != end; ++s)
7
v.push_back((*s) mod 2^32);

template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);

8
Mandates: iterator_traits<RandomAccessIterator>::value_type is an unsigned integer type capable of accommodating 32-bit quantities.

9
Preconditions: RandomAccessIterator meets the Cpp17RandomAccessIterator requirements (25.3.5.7) and the requirements of a mutable iterator.

10
Effects: Does nothing if begin == end. Otherwise, with s = v.size() and n = end - begin, fills the supplied range [begin, end) according to the following algorithm in which each operation is to be carried out modulo $2^{32}$, each indexing operator applied to begin is to be taken modulo n, and $T(x)$ is defined as $x \ xor (x \ shift 27)$:

9.1
— By way of initialization, set each element of the range to the value 0x8b8b8b8b. Additionally, for use in subsequent steps, let $p = (n - t) / 2$ and let $q = p + t$, where

9.1.1 $t = (n \geq 623) \ ? 11 : (n \geq 68) \ ? 7 : (n \geq 39) \ ? 5 : (n \geq 7) \ ? 3 : (n - 1) / 2$;

9.2
— With m as the larger of s + 1 and n, transform the elements of the range: iteratively for $k = 0, \ldots, m - 1$, calculate values

9.2.1
$$r_1 = 1664525 \cdot T \begin{bmatrix} \begin{array}{c} \text{begin}[k] \ xor \ begin[k + p] \ xor \ begin[k - 1] \end{array} \end{bmatrix}$$

9.2.2
$$r_2 = \begin{cases} s, & k = 0 \\ k \ mod \ n + v[k - 1], & 0 < k \leq s \\ k \ mod \ n, & s < k \end{cases}$$

and, in order, increment begin[k + p] by $r_1$, increment begin[k + q] by $r_2$, and set begin[k] to $r_2$.

9.3
— Transform the elements of the range again, beginning where the previous step ended: iteratively for $k = m, \ldots, m + n - 1$, calculate values

9.3.1
$$r_3 = 1566083941 \cdot T \begin{bmatrix} \begin{array}{c} \text{begin}[k] + \ begin[k + p] + \ begin[k - 1] \end{array} \end{bmatrix}$$

9.3.2
$$r_4 = r_3 - (k \ mod \ n)$$

and, in order, update begin[k + p] by xoring it with $r_3$, update begin[k + q] by xoring it with $r_4$, and set begin[k] to $r_4$.

10
Throws: What and when RandomAccessIterator operations of begin and end throw.

size_t size() const noexcept;

11
Returns: The number of 32-bit units that would be returned by a call to param().

12
Complexity: Constant time.
template<class OutputIterator>
void param(OutputIterator dest) const;

Mandates: Values of type result_type are writable (25.3.1) to dest.

Preconditions: OutputIterator meets the Cpp17OutputIterator requirements (25.3.5.4).

Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

\[
\text{copy(v.begin(), v.end(), dest);} \\
\]

Throws: What and when OutputIterator operations of dest throw.

28.5.8.2 Function template generate_canonical

\[
\text{template<class RealType, size_t digits, class URBG>}
\]

\[
\text{RealType generate_canonical(URBG& g);} \\
\]

Let

\[
\begin{align}
& r \text{ be numeric_limits<RealType>::radix}, \\
& R \text{ be } \text{g}.\text{max}() - \text{g}.\text{min}() + 1, \\
& d \text{ be the smaller of digits and numeric_limits<RealType>::digits},^229 \\
& k \text{ be the smallest integer such that } R^k \geq r^d, \text{ and} \\
& x \text{ be } \left\lfloor \frac{R^k}{r^d} \right\rfloor.
\end{align}
\]

An attempt is \( k \) invocations of \( g() \) to obtain values \( g_0, \ldots, g_{k-1} \), respectively, and the calculation of a quantity

\[
S = \sum_{i=0}^{k-1} (g_i - \text{g}.\text{min}()) \cdot R^i \\
\]

Effects: Attempts are made until \( S < xr^d \).

[Note 1: When \( R \) is a power of \( r \), precisely one attempt is made. — end note]

Returns: \( \frac{S}{x} / r^d \).

[Note 2: The return value \( c \) satisfies \( 0 \leq c < 1 \). — end note]

Throws: What and when \( g \) throws.

Complexity: Exactly \( k \) invocations of \( g \) per attempt.

[Note 3: If the values \( g_i \) produced by \( g \) are uniformly distributed, the instantiation’s results are distributed as uniformly as possible. Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution. — end note]

[Note 4: When \( R \) is a power of \( r \), an implementation can avoid using an arithmetic type that is wider than the output when computing \( S \). — end note]

28.5.9 Random number distribution class templates

28.5.9.1 In general

Each type instantiated from a class template specified in this subclause 28.5.9 meets the requirements of a random number distribution (28.5.3.6) type.

Descriptions are provided in this subclause 28.5.9 only for distribution operations that are not described in 28.5.3.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

The algorithms for producing each of the specified distributions are implementation-defined.

The value of each probability density function \( p(z) \) and of each discrete probability function \( P(z_i) \) specified in this subclause is 0 everywhere outside its stated domain.

\[229\] \( d \) is introduced to avoid any attempt to produce more bits of randomness than can be held in RealType.
28.5.9.2 Uniform distributions

28.5.9.2.1 Class template uniform_int_distribution

A uniform_int_distribution random number distribution produces random integers \( i, \ a \leq i \leq b \), distributed according to the constant discrete probability function

\[
P(i \mid a, b) = 1/(b - a + 1).
\]

\[
\text{namespace std \{}
\]
\[
\text{template<class IntType = int>}
\]
\[
\text{class uniform_int_distribution \{}
\]
\[
\text{public:}
\]
\[
\text{using result_type = IntType;}
\]
\[
\text{using param_type = unspecified;}
\]
\[
\text{uniform_int_distribution() : uniform_int_distribution(0) \{\}}
\]
\[
\text{explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());}
\]
\[
\text{explicit uniform_int_distribution(const param_type& parm);} \;
\]
\[
\text{void reset();}
\]
\[
\text{friend bool operator==(const uniform_int_distribution& x, const uniform_int_distribution& y);} \;
\]
\[
\text{template<class URBG>}
\]
\[
\text{result_type operator()(URBG& g);} \;
\]
\[
\text{template<class URBG>}
\]
\[
\text{result_type operator()(URBG& g, const param_type& parm);} \;
\]
\[
\text{// property functions}
\]
\[
\text{result_type a() const;}
\]
\[
\text{result_type b() const;}
\]
\[
\text{param_type param() const;}
\]
\[
\text{void param(const param_type& parm);} \;
\]
\[
\text{result_type min() const;}
\]
\[
\text{result_type max() const;}
\]
\[
\text{// inserters and extractors}
\]
\[
\text{template<class charT, class traits>}
\]
\[
\text{friend basic_ostream<charT, traits>&}
\]
\[
\text{friend basic_ostream<charT, traits>& os, const uniform_int_distribution& x);} \;
\]
\[
\text{template<class charT, class traits>}
\]
\[
\text{friend basic_istream<charT, traits>&}
\]
\[
\text{friend basic_istream<charT, traits>& is, uniform_int_distribution& x);} \;
\]
\[
\text{\};}
\]
\[
\text{explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());}
\]

2 Preconditions: \( a \leq b \).

3 Remarks: \( a \) and \( b \) correspond to the respective parameters of the distribution.

result_type a() const;

4 Returns: The value of the \( a \) parameter with which the object was constructed.

result_type b() const;

5 Returns: The value of the \( b \) parameter with which the object was constructed.

28.5.9.2.2 Class template uniform_real_distribution

A uniform_real_distribution random number distribution produces random numbers \( x, a \leq x < b \), distributed according to the constant probability density function

\[
p(x \mid a, b) = 1/(b - a).
\]
namespace std {
    template<class RealType = double>
    class uniform_real_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        uniform_real_distribution() : uniform_real_distribution(0.0) {}
        explicit uniform_real_distribution(RealType a, RealType b = 1.0);
        explicit uniform_real_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const uniform_real_distribution& x,
                              const uniform_real_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        result_type a() const;
        result_type b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const uniform_real_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, uniform_real_distribution& x);
    }
}

explicit uniform_real_distribution(RealType a, RealType b = 1.0);

Preconditions: \( a \leq b \) and \( b - a \leq \text{numeric_limits<RealType>::max()} \).

Remarks: \( a \) and \( b \) correspond to the respective parameters of the distribution.

result_type a() const;

Returns: The value of the \( a \) parameter with which the object was constructed.

result_type b() const;

Returns: The value of the \( b \) parameter with which the object was constructed.

28.5.9.3 Bernoulli distributions

28.5.9.3.1 Class bernoulli_distribution

A bernoulli_distribution random number distribution produces bool values \( b \) distributed according to the discrete probability function

\[
P(b|p) = \begin{cases} 
p & \text{if } b = \text{true}, \\
1 - p & \text{if } b = \text{false}.
\end{cases}
\]
namespace std {

class bernoulli_distribution {
public:
   // types
   using result_type = bool;
   using param_type = unspecified;

   // constructors and reset functions
   bernoulli_distribution() : bernoulli_distribution(0.5) {}
   explicit bernoulli_distribution(double p);
   explicit bernoulli_distribution(const param_type& parm);
   void reset();

   // equality operators
   friend bool operator==(const bernoulli_distribution& x, const bernoulli_distribution& y);

   // generating functions
   template<class URBG>
   result_type operator()(URBG& g);
   template<class URBG>
   result_type operator()(URBG& g, const param_type& parm);

   // property functions
   double p() const;
   param_type param() const;
   void param(const param_type& parm);
   result_type min() const;
   result_type max() const;

   // inserters and extractors
   template<class charT, class traits>
   friend basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const bernoulli_distribution& x);
   template<class charT, class traits>
   friend basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bernoulli_distribution& x);
};

explicit bernoulli_distribution(double p);

Preconditions: 0 ≤ p ≤ 1.

Remarks: p corresponds to the parameter of the distribution.

double p() const;

Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.2 Class template binomial_distribution

A binomial_distribution random number distribution produces integer values i ≥ 0 distributed according to the discrete probability function

\[ P(i \mid t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i}. \]

namespace std {

template<class IntType = int>
class binomial_distribution {
public:
   // types
   using result_type = IntType;
   using param_type = unspecified;

};

§ 28.5.9.3.2
// constructors and reset functions
binomial_distribution() : binomial_distribution(1) {}
explicit binomial_distribution(IntType t, double p = 0.5);
explicit binomial_distribution(const param_type& parm);
void reset();

// equality operators
friend bool operator==(const binomial_distribution& x, const binomial_distribution& y);

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
IntType t() const;
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const binomial_distribution& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, binomial_distribution& x);

explicit binomial_distribution(IntType t, double p = 0.5);

// Preconditions:
0 \leq p \leq 1 and 0 \leq t.

// Remarks:
t and p correspond to the respective parameters of the distribution.

IntType t() const;
Returns: The value of the t parameter with which the object was constructed.

double p() const;
Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.3 Class template geometric_distribution

A geometric_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i \mid p) = p \cdot (1 - p)^i .
\]

namespace std {
    template<class IntType = int>
class geometric_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    geometric_distribution() : geometric_distribution(0.5) {}
    explicit geometric_distribution(double p);
    explicit geometric_distribution(const param_type& parm);
    void reset();
};
friend bool operator==(const geometric_distribution& x, const geometric_distribution& y);

friend bool operator==(const negative_binomial_distribution& x, const negative_binomial_distribution& y);

// generating functions
template<class URBG>
result_type operator()(URBG& g);

template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const geometric_distribution& x);

template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, geometric_distribution& x);

explicit geometric_distribution(double p);

Preconditions: 0 < p < 1.
Remarks: p corresponds to the parameter of the distribution.

double p() const;

Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.4 Class template negative_binomial_distribution

A negative_binomial_distribution random number distribution produces random integers \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | k, p) = \binom{k+i-1}{i} \cdot p^k \cdot (1-p)^i.
\]

[Note 1: This implies that \( P(i | k, p) \) is undefined when \( p = 1 \). —end note]
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    IntType k() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const negative_binomial_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, negative_binomial_distribution& x);

explicit negative_binomial_distribution(IntType k, double p = 0.5);

2 Preconditions: 0 < p ≤ 1 and 0 < k.
3 Remarks: k and p correspond to the respective parameters of the distribution.

IntType k() const;
4 Returns: The value of the k parameter with which the object was constructed.

double p() const;
5 Returns: The value of the p parameter with which the object was constructed.

28.5.9.4 Poisson distributions [rand.dist.pois]
28.5.9.4.1 Class template poisson_distribution [rand.dist.pois.poisson]
1 A poisson_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i \mid \mu) = \frac{e^{-\mu} \mu^i}{i!}.
\]

The distribution parameter \( \mu \) is also known as this distribution’s mean.

template<class IntType = int>
class poisson_distribution
{
    public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    poisson_distribution() : poisson_distribution(1.0) {}
    explicit poisson_distribution(double mean);
    explicit poisson_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const poisson_distribution& x, const poisson_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);
// property functions
double mean() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<
class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const poisson_distribution& x);
template<
class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, poisson_distribution& x);
};
explicit poisson_distribution(double mean);

Preconditions: 0 < mean.
Remarks: mean corresponds to the parameter of the distribution.

double mean() const;
Returns: The value of the mean parameter with which the object was constructed.

§ 28.5.9.4.2 Class template exponential_distribution
An exponential_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid \lambda) = \lambda e^{-\lambda x} .
\]

namespace std {
template<class RealType = double>
class exponential_distribution {
public:
// types
using result_type = RealType;
using param_type = unspecified;

// constructors and reset functions
explicit exponential_distribution(); exponential_distribution(1.0) {}
explicit exponential_distribution(RealType lambda);
explicit exponential_distribution(const param_type& parm);
void reset();

// equality operators
friend bool operator==(const exponential_distribution& x, const exponential_distribution& y);

// generating functions
template<
class URBG>
result_type operator()(URBG& g);
template<
class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType lambda() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<
class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const exponential_distribution& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, exponential_distribution& x);
};

explicit exponential_distribution(RealType lambda);

Preconditions: 0 < lambda.

Remarks: lambda corresponds to the parameter of the distribution.

RealType lambda() const;

Returns: The value of the lambda parameter with which the object was constructed.

28.5.9.4.3 Class template gamma_distribution [rand.dist.pois.gamma]

A gamma_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha-1}.
\]

namespace std {
    template<class RealType = double>
    class gamma_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        gamma_distribution() : gamma_distribution(1.0) {};
        explicit gamma_distribution(RealType alpha, RealType beta = 1.0);
        explicit gamma_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const gamma_distribution& x, const gamma_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType alpha() const;
        RealType beta() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const gamma_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, gamma_distribution& x);
    };
explicit gamma_distribution(RealType alpha, RealType beta = 1.0);

Preconditions: 0 < alpha and 0 < beta.

Remarks: alpha and beta correspond to the parameters of the distribution.

RealType alpha() const;

Returns: The value of the alpha parameter with which the object was constructed.

RealType beta() const;

Returns: The value of the beta parameter with which the object was constructed.

28.5.9.4.4 Class template weibull_distribution

A weibull_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
 p(x | a, b) = \frac{a}{b} \left( \frac{x}{b} \right)^{a-1} \exp \left( - \left( \frac{x}{b} \right)^a \right).
\]

namespace std {
  template<class RealType = double>
  class weibull_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    weibull_distribution() : weibull_distribution(1.0) {}
    explicit weibull_distribution(RealType a, RealType b = 1.0);
    explicit weibull_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const weibull_distribution& x, const weibull_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType a() const;
    RealType b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& os, const weibull_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
      operator>>(basic_istream<charT, traits>& is, weibull_distribution& x);
  };
}

explicit weibull_distribution(RealType a, RealType b = 1.0);

Preconditions: 0 < a and 0 < b.

Remarks: a and b correspond to the respective parameters of the distribution.
RealType a() const;

    Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

    Returns: The value of the b parameter with which the object was constructed.

28.5.9.4.5 Class template extreme_value_distribution [rand.dist.pois.extreme]

An extreme_value_distribution random number distribution produces random numbers x distributed according to the probability density function

\[
p(x | a, b) = \frac{1}{b} \exp \left( \frac{a - x}{b} - \exp \left( \frac{a - x}{b} \right) \right).
\]

namespace std {

template<class RealType = double>
    class extreme_value_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        extreme_value_distribution() : extreme_value_distribution(0.0) {} // default constructor
        explicit extreme_value_distribution(RealType a, RealType b = 1.0);
        explicit extreme_value_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const extreme_value_distribution& x, const extreme_value_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const extreme_value_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, extreme_value_distribution& x);
    };
}

explicit extreme_value_distribution(RealType a, RealType b = 1.0);

Preconditions: 0 < b.
Remarks: a and b correspond to the respective parameters of the distribution.

230) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.
RealType a() const;

Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

Returns: The value of the b parameter with which the object was constructed.

28.5.9.5 Normal distributions

28.5.9.5.1 Class template normal_distribution

A normal_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right).
\]

The distribution parameters \( \mu \) and \( \sigma \) are also known as this distribution’s mean and standard deviation.

namespace std {
    template<class RealType = double>
    class normal_distribution {
        public:
            // types
            using result_type = RealType;
            using param_type = unspecified;

            // constructors and reset functions
            normal_distribution() : normal_distribution(0.0) {};
            explicit normal_distribution(RealType mean, RealType stddev = 1.0);
            explicit normal_distribution(const param_type& parm);
            void reset();

            // equality operators
            friend bool operator==(const normal_distribution& x, const normal_distribution& y);

            // generating functions
            template<class URBG>
            result_type operator()(URBG& g);
            template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

            // property functions
            RealType mean() const;
            RealType stddev() const;
            param_type param() const;
            void param(const param_type& parm);
            result_type min() const;
            result_type max() const;

            // inserters and extractors
            template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const normal_distribution& x);
            template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, normal_distribution& x);
        }
    }

    explicit normal_distribution(RealType mean, RealType stddev = 1.0);

    Preconditions: \( 0 < \text{stddev} \).

    Remarks: \( \text{mean} \) and \( \text{stddev} \) correspond to the respective parameters of the distribution.

    RealType mean() const;

    Returns: The value of the \( \text{mean} \) parameter with which the object was constructed.
RealType stddev() const;

Returns: The value of the \texttt{stddev} parameter with which the object was constructed.

\section*{28.5.9.5.2 Class template \texttt{lognormal_distribution}}

A \texttt{lognormal_distribution} random number distribution produces random numbers \(x > 0\) distributed according to the probability density function

\[
p(x \mid m, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(\frac{-(\ln x - m)^2}{2s^2}\right).
\]

namespace std {
  template<class RealType = double>
  class lognormal_distribution {
    public:
      // types
      using result_type = RealType;
      using param_type = unspecified;

      // constructor and reset functions
      lognormal_distribution() : lognormal_distribution(0.0) {};
      explicit lognormal_distribution(RealType m, RealType s = 1.0);
      explicit lognormal_distribution(const param_type& parm);
      void reset();

      // equality operators
      friend bool operator==(const lognormal_distribution& x, const lognormal_distribution& y);

      // generating functions
      template<class URBG>
      result_type operator()(URBG& g);
      template<class URBG>
      result_type operator()(URBG& g, const param_type& parm);

      // property functions
      RealType m() const;
      RealType s() const;
      param_type param() const;
      void param(const param_type& parm);
      result_type min() const;
      result_type max() const;

      // inserters and extractors
      template<class charT, class traits>
      friend basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& os, const lognormal_distribution& x);
      template<class charT, class traits>
      friend basic_istream<charT, traits>&
      operator>>(basic_istream<charT, traits>& is, lognormal_distribution& x);
  };
}

explicit lognormal_distribution(RealType m, RealType s = 1.0);

Preconditions: \(0 < s\).

Remarks: \(m\) and \(s\) correspond to the respective parameters of the distribution.

RealType m() const;

Returns: The value of the \(m\) parameter with which the object was constructed.

RealType s() const;

Returns: The value of the \(s\) parameter with which the object was constructed.
28.5.9.5.3 Class template chi_squared_distribution

A chi_squared_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid n) = \frac{x^{(n/2)-1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}}.
\]

namespace std {
    template<class RealType = double>
    class chi_squared_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        chi_squared_distribution() : chi_squared_distribution(1.0) {}
        explicit chi_squared_distribution(RealType n);
        explicit chi_squared_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const chi_squared_distribution& x, const chi_squared_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const chi_squared_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, chi_squared_distribution& x);
    }

    explicit chi_squared_distribution(RealType n);
}

Preconditions: 0 < n.
Remarks: n corresponds to the parameter of the distribution.

RealType n() const;
Returns: The value of the n parameter with which the object was constructed.

28.5.9.5.4 Class template cauchy_distribution

A cauchy_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid a, b) = \left( \pi b \left( 1 + \left( \frac{x - a}{b} \right)^2 \right) \right)^{-1}.
\]

§ 28.5.9.5.4
namespace std {
    template<class RealType = double>
    class cauchy_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        cauchy_distribution() : cauchy_distribution(0.0) {}
        explicit cauchy_distribution(RealType a, RealType b = 1.0);
        explicit cauchy_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const cauchy_distribution& x, const cauchy_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const cauchy_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, cauchy_distribution& x);
    };

explicit cauchy_distribution(RealType a, RealType b = 1.0);

2 Preconditions: 0 < b.

3 Remarks: a and b correspond to the respective parameters of the distribution.

RealType a() const;

4 Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

5 Returns: The value of the b parameter with which the object was constructed.

28.5.9.5.5  Class template fisher_f_distribution

A fisher_f_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x | m,n) = \frac{\Gamma((m+n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left(\frac{m}{n}\right)^{m/2} \cdot x^{(m/2)-1} \cdot \left(1 + \frac{mx}{n}\right)^{-(m+n)/2}.
\]
namespace std {

template<class RealType = double>
class fisher_f_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    fisher_f_distribution() : fisher_f_distribution(1.0) {}  // constructor
    explicit fisher_f_distribution(RealType m, RealType n = 1.0);
    explicit fisher_f_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const fisher_f_distribution& x, const fisher_f_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType m() const;
    RealType n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const fisher_f_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, fisher_f_distribution& x);
};

explicit fisher_f_distribution(RealType m, RealType n = 1);

Preconditions: 0 < m and 0 < n.

Remarks: m and n correspond to the respective parameters of the distribution.

RealType m() const;
Returns: The value of the m parameter with which the object was constructed.

RealType n() const;
Returns: The value of the n parameter with which the object was constructed.

28.5.9.5.6 Class template student_t_distribution [rand.dist.norm.t]

A student_t_distribution random number distribution produces random numbers x distributed according to the probability density function

\[ p(x | n) = \frac{1}{\sqrt{n\pi}} \cdot \frac{\Gamma((n+1)/2)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-\frac{(n+1)/2}{2}}. \]
namespace std {
    template<class RealType = double>
    class student_t_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        student_t_distribution() : student_t_distribution(1.0) {} explicit student_t_distribution(RealType n);
        explicit student_t_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const student_t_distribution& x, const student_t_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const student_t_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, student_t_distribution& x);
    }

    explicit student_t_distribution(RealType n);

    Preconditions: 0 < n.

    Remarks: n corresponds to the parameter of the distribution.

    RealType n() const;

    Returns: The value of the n parameter with which the object was constructed.

28.5.9.6 Sampling distributions
28.5.9.6.1 Class template discrete_distribution

A discrete_distribution random number distribution produces random integers \(i, 0 \leq i < n\), distributed according to the discrete probability function

\[ P(i | p_0, \ldots, p_{n-1}) = p_i . \]

2 Unless specified otherwise, the distribution parameters are calculated as: \(p_k = w_k / S\) for \(k = 0, \ldots, n - 1\), in which the values \(w_k\), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \(0 < S = w_0 + \cdots + w_{n-1}\).
namespace std {

    template<class IntType = int>
    class discrete_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructor and reset functions
        discrete_distribution();
        template<class InputIterator>
        discrete_distribution(InputIterator firstW, InputIterator lastW);
        discrete_distribution(initializer_list<double> wl);
        template<class UnaryOperation>
        discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
        explicit discrete_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const discrete_distribution& x, const discrete_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<double> probabilities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const discrete_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, discrete_distribution& x);
    };

    discrete_distribution();

Effects: Constructs a discrete_distribution object with \( n = 1 \) and \( p_0 = 1 \).

[Note 1: Such an object will always deliver the value 0. — end note]

    template<class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);

Mandates: is_convertible_v<iterator_traits<InputIterator>::value_type, double> is true.

Preconditions: InputIterator meets the Cpp17InputIterator requirements (25.3.5.3). If firstW ==
lastW, let \( n = 1 \) and \( w_0 = 1 \). Otherwise, \([\text{firstW, lastW}]\) forms a sequence \( w \) of length \( n > 0 \).

Effects: Constructs a discrete_distribution object with probabilities given by the formula above.

discrete_distribution(initializer_list<double> wl);

Effects: Same as discrete_distribution(wl.begin(), wl.end()).

template<class UnaryOperation>
    discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation& , double> is true.
Preconditions: If \( \text{nw} = 0 \), let \( n = 1 \), otherwise let \( n = \text{nw} \). The relation \( 0 < \delta = (\text{xmax} - \text{xmin})/n \) holds.

Effects: Constructs a \textit{discrete_distribution} object with probabilities given by the formula above, using the following values: If \( \text{nw} = 0 \), let \( w_0 = 1 \). Otherwise, let \( w_k = f_w(x_{\text{min}} + k \cdot \delta + \delta/2) \) for \( k = 0, \ldots, n-1 \).

Complexity: The number of invocations of \( f_w \) does not exceed \( n \).

```cpp
vector<double> probabilities() const;
```

Returns: A \textit{vector<double>} whose \textit{size} member returns \( n \) and whose \textit{operator[]} member returns \( p_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n-1 \).

### 28.5.9.6.2 Class template piecewise_constant_distribution

A \textit{piecewise_constant_distribution} random number distribution produces random numbers \( x, \ b_0 \leq x < b_n \), uniformly distributed over each subinterval \( [b_i, b_{i+1}) \) according to the probability density function

\[
p(x|b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \quad \text{for} \quad b_i \leq x < b_{i+1},
\]

The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s \textit{interval boundaries}, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n-1 \). Unless specified otherwise, the remaining \( n \) distribution parameters are calculated as:

\[
p_k = \frac{w_k}{S \cdot (b_{k+1} - b_k)} \quad \text{for} \quad k = 0, \ldots, n-1,
\]

in which the values \( w_k \), commonly known as the \textit{weights}, shall be non-negative, non-NaNa, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = w_0 + \cdots + w_{n-1}.
\]
piecewise_constant_distribution();

Effects: Constructs a piecewise_constant_distribution object with \( n = 1, \rho_0 = 1, b_0 = 0, \) and \( b_1 = 1. \)

template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB, InputIteratorW firstW);

Mandates: Both of
\[ \text{is_convertible_v<iterator_traits<InputIteratorB>::value_type, double>} \]
\[ \text{is_convertible_v<iterator_traits<InputIteratorW>::value_type, double>} \]
are true.

Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (25.3.5.3). If firstB == lastB or ++firstB == lastB, let \( n = 1, w_0 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, \([\text{firstB,lastB}]\) forms a sequence \( b \) of length \( n + 1, \) the length of the sequence \( w \) starting from firstW is at least \( n, \) and any \( w_k \) for \( k \geq n \) are ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let \( n = 1, w_0 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, let \([\text{bl.begin()}, \text{bl.end()}]\) form a sequence \( b_0, \ldots, b_n, \) and let \( w_k = \text{fw}((b_{k+1}+b_k)/2) \) for \( k = 0, \ldots, n - 1. \)

Complexity: The number of invocations of \( \text{fw} \) does not exceed \( n. \)

template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Preconditions: If \( nw = 0, \) let \( n = 1, \) otherwise let \( n = nw. \) The relation \( 0 < \delta = (\text{xmax} - \text{xmin})/n \) holds.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: Let \( b_k = \text{xmin} + k \cdot \delta \) for \( k = 0, \ldots, n, \) and \( w_k = \text{fw}(b_k + \delta/2) \) for \( k = 0, \ldots, n - 1. \)

Complexity: The number of invocations of \( \text{fw} \) does not exceed \( n. \)

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n. \)

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( p_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n - 1. \)

28.5.9.6.3 Class template piecewise_linear_distribution

A piecewise_linear_distribution random number distribution produces random numbers \( x, b_0 \leq x < b_n, \) distributed over each subinterval \([b_i, b_{i+1})\) according to the probability density function
\[
p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}.\]
The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s *interval boundaries*, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n + 1 \) distribution parameters are calculated as \( \rho_k = w_k / S \) for \( k = 0, \ldots, n \), in which the values \( w_k \), commonly known as the *weights at boundaries*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = \frac{1}{2} \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).
\]

```cpp
namespace std {
    template<class RealType = double>
    class piecewise_linear_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_linear_distribution();
        template<class InputIteratorB, class InputIteratorW>
        piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                       InputIteratorW firstW);
        template<class UnaryOperation>
        piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
        piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
        explicit piecewise_linear_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const piecewise_linear_distribution& x,
                               const piecewise_linear_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const piecewise_linear_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, piecewise_linear_distribution& x);
    }
}
```

Effects: Constructs a `piecewise_linear_distribution` object with \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).
template<class InputIteratorB, class InputIteratorW>
.piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB, InputIteratorW firstW);

.Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

.Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (25.3.5.3). If firstB == lastB or ++firstB == lastB, let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, \([firstB, lastB]\) forms a sequence \( b \) of length \( n + 1, \) the length of the sequence \( w \) starting from firstW is at least \( n + 1, \) and any \( w_k \) for \( k \geq n + 1 \) are ignored by the distribution.

.Effects: Constructs a piecewise_linear_distribution object with parameters as specified above.

template<class UnaryOperation>
.piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);

.Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

.Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1. \) Otherwise, let \([bl.begin(), bl.end()]\) form a sequence \( b_0, \ldots, b_n, \) and let \( w_k = fw(b_k) \) for \( k = 0, \ldots, n. \)

.Complexity: The number of invocations of \( fw \) does not exceed \( n + 1. \)

template<class UnaryOperation>
.piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

.Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

.Preconditions: If \( nw = 0, \) let \( n = 1, \) otherwise let \( n = nw. \) The relation \( 0 < \delta = (xmax - xmin)/n \) holds.

.Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from the following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n, \) and \( w_k = fw(b_k) \) for \( k = 0, \ldots, n. \)

.Complexity: The number of invocations of \( fw \) does not exceed \( n + 1. \)

vector<result_type> intervals() const;

.Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n. \)

vector<result_type> densities() const;

.Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( p_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n. \)

28.5.10 Low-quality random number generation [c.math.rand]

[Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

int rand();

void srand(unsigned int seed);

.Effects: The rand and srand functions have the semantics specified in the C standard library.

.Remarks: The implementation may specify that particular library functions may call rand. It is implementation-defined whether the rand function may introduce data races (16.4.6.10).

[Note 2: The other random number generation facilities in this document (28.5) are often preferable to rand, because rand’s underlying algorithm is unspecified. Use of rand therefore continues to be non-portable, with unpredictable and oft-questionable quality and performance. — end note]

template<class T>
unspecified
2 end(const valarray<T>& v);
}

The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.\(^\text{231}\)

Implementations introducing such replacement types shall provide additional functions and operators as follows:

\begin{enumerate}
\item[4.1] — for every function taking a `const valarray<T>&` other than `begin` and `end` (28.6.10), identical functions taking the replacement types shall be added;
\item[4.2] — for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.
\end{enumerate}

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (17.6.4.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

### 28.6.2 Class template `valarray`

#### [template.valarray]

#### 28.6.2.1 Overview

[template.valarray.overview]

```cpp
namespace std {
    template<
class T> class valarray {
    public:
        using value_type = T;

        // 28.6.2.2, construct/destroy
        valarray();
        explicit valarray(size_t);
        valarray(const T&, size_t);
        valarray(const T*, size_t);
        valarray(const valarray&);
        valarray(valarray&&) noexcept;
        valarray(const slice_array<T>&);
        valarray(const gslice_array<T>&);
        valarray(const mask_array<T>&);
        valarray(const indirect_array<T>&);
        valarray(initializer_list<T>);
        ~valarray();
    }

\text{\textsuperscript{231}} Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for valarray expressions.
```
// 28.6.2.3, assignment
valarray& operator=(const valarray&);
valarray& operator=(valarray&&) noexcept;
valarray& operator=(initializer_list<T>);
valarray& operator=(const T&);
valarray& operator=(const slice_array<T>);
valarray& operator=(const gslice_array<T>);
valarray& operator=(const mask_array<T>);
valarray& operator=(const indirect_array<T>);

// 28.6.2.4, element access
const T& operator[](size_t) const;
T& operator[](size_t);

// 28.6.2.5, subset operations
valarray operator[](slice) const;
slice_array<T> operator[](slice);
valarray operator[](const gslice&);
gslice_array<T> operator[](const gslice&);
valarray operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
valarray operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 28.6.2.6, unary operators
valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

// 28.6.2.7, compound assignment
valarray& operator*=(const T&);
valarray& operator/=(const T&);
valarray& operator%=(const T&);
valarray& operator+=(const T&);
valarray& operator-=(const T&);
valarray& operator^=(const T&);
valarray& operator&=(const T&);
valarray& operator|=(const T&);
valarray& operator<<=(const T&);
valarray& operator>>=(const T&);
valarray& operator*= (const valarray&);
valarray& operator/= (const valarray&);
valarray& operator%= (const valarray&);
valarray& operator+= (const valarray&);
valarray& operator-= (const valarray&);
valarray& operator^= (const valarray&);
valarray& operator|= (const valarray&);
valarray& operator&= (const valarray&);
valarray& operator<<=(const valarray&);
valarray& operator>>=(const valarray&);

// 28.6.2.8, member functions
void swap(valarray&) noexcept;
size_t size() const;
T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;
The class template `valarray<T>` is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type `valarray<T>` is referred to as an “array” throughout the remainder of 28.6. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.\(^{232}\)

### 28.6.2.2 Constructors

[Valarray.cons]

```cpp
valarray();
```

**Effects:** Constructs a `valarray` that has zero length.\(^{233}\)

```cpp
explicit valarray(size_t n);
```

**Effects:** Constructs a `valarray` that has length `n`. Each element of the array is value-initialized (9.4).

```cpp
valarray(const T& v, size_t n);
```

**Effects:** Constructs a `valarray` that has length `n`. Each element of the array is initialized with `v`.

```cpp
valarray(const T* p, size_t n);
```

**Preconditions:** `\([p, p + n)\)` is a valid range.

**Effects:** Constructs a `valarray` that has length `n`. The values of the elements of the array are initialized with the first `n` values pointed to by the first argument.\(^{234}\)

```cpp
valarray(const valarray& v);
```

**Effects:** Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.\(^{235}\)

```cpp
valarray(valarray&& v) noexcept;
```

**Effects:** Constructs a `valarray` that has the same length as `v`. The elements are initialized with the values of the corresponding elements of `v`.

**Complexity:** Constant.

```cpp
valarray(initializer_list<T> il);
```

**Effects:** Equivalent to `valarray(il.begin(), il.size())`.

```cpp
valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);
```

These conversion constructors convert one of the four reference templates to a `valarray`.

```cpp
~valarray();
```

**Effects:** The destructor is applied to every element of `*this`; an implementation may return all allocated memory.

\(^{232}\) The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the `valarray` template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

\(^{233}\) This default constructor is essential, since arrays of `valarray` can be useful. After initialization, the length of an empty array can be increased with the `resize` member function.

\(^{234}\) This constructor is the preferred method for converting a C array to a `valarray` object.

\(^{235}\) This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
28.6.2.3 Assignment

valarray& operator=(const valarray& v);
1 Effects: Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizes *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.
2 Postconditions: size() == v.size().
3 Returns: *this.

valarray& operator=(valarray&& v) noexcept;
4 Effects: *this obtains the value of v. The value of v after the assignment is not specified.
5 Returns: *this.
6 Complexity: Linear.

valarray& operator=(initializer_list<T> il);
7 Effects: Equivalent to: return *this = valarray(il);

valarray& operator=(const T& v);
8 Effects: Assigns v to each element of *this.
9 Returns: *this.

valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);
10 Preconditions: The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.
11 These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

28.6.2.4 Element access

const T& operator[](size_t n) const;
T& operator[](size_t n);
1 Preconditions: n < size() is true.
2 Returns: A reference to the corresponding element of the array.
[Note 1: The expression a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]
3 Remarks: The expression addressof(a[i+j]) == addressof(a[i]) + j evaluates to true for all size_t i and size_t j such that i+j < a.size().
4 The expression addressof(a[i]) ! = addressof(b[j]) evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size().
[Note 2: This property indicates an absence of aliasing and can be used to advantage by optimizing compilers. Compilers can take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]
5 The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (28.6.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

28.6.2.5 Subset operations

The member operator[] is overloaded to provide several ways to select sequences of elements from among those controlled by *this. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new valarray object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of operator=
and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case
the selected element(s) shall exist.

valarray operator[](slice slicearr) const;

2  Returns: A valarray containing those elements of the controlled sequence designated by slicearr.

[Example 1:
  const valarray<char> v0("abcdefgijklmnop", 16);
  // v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
  — end example]

slice_array<T> operator[](slice slicearr);

3  Returns: An object that holds references to elements of the controlled sequence selected by slicearr.

[Example 2:
  valarray<char> v0("abcdefgijklmnop", 16);
  valarray<char> v1("ABCDE", 5);
  v0[slice(2, 5, 3)] = v1;
  // v0 == valarray<char>("abAdeBghCjkDmnEp", 16);
  — end example]

valarray operator[](const gslice& gslicearr) const;

4  Returns: A valarray containing those elements of the controlled sequence designated by gslicearr.

[Example 3:
  const valarray<char> v0("abcdefgijklmnop", 16);
  const size_t lv[] = {2, 3};
  const size_t dv[] = {7, 2};
  const valarray<size_t> len(lv, 2), str(dv, 2);
  // v0[gslice(3, len, str)] returns
  // valarray<char>("dfhkmo", 6)
  — end example]

gslice_array<T> operator[](const gslice& gslicearr);

5  Returns: An object that holds references to elements of the controlled sequence selected by gslicearr.

[Example 4:
  valarray<char> v0("abcdefgijklmnop", 16);
  valarray<char> v1("ABCDEF", 6);
  const size_t lv[] = {2, 3};
  const size_t dv[] = {7, 2};
  const valarray<size_t> len(lv, 2), str(dv, 2);
  v0[gslice(3, len, str)] = v1;
  // v0 == valarray<char>("abcAeBghCijDlEnFp", 16)
  — end example]

valarray operator[](const valarray<bool>& boolarr) const;

6  Returns: A valarray containing those elements of the controlled sequence designated by boolarr.

[Example 5:
  const valarray<char> v0("abcdefgijklmnop", 16);
  const bool vb[] = {false, false, true, true, false, true};
  // v0[valarray<bool>(vb, 6)] returns
  // valarray<char>("cdf", 3)
  — end example]

mask_array<T> operator[](const valarray<bool>& boolarr);

7  Returns: An object that holds references to elements of the controlled sequence selected by boolarr.

[Example 6:
  valarray<char> v0("abcdefgijklmnop", 16);
valarray operator[](const valarray&lt;size_t&gt;& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr.

[Example 7:
  const valarray&lt;char&gt; v0("abcdefghijklmnop", 16);
  const size_t vi[] = { 7, 5, 2, 3, 8 };
  // v0[valarray&lt;size_t&gt;(vi, 5)] returns
  // valarray&lt;char&gt;("hfcdi", 5)
  —end example]

indirect_array&lt;T&gt; operator[](const valarray&lt;size_t&gt;& indarr);

Returns: An object that holds references to elements of the controlled sequence selected by indarr.

[Example 8:
  valarray&lt;char&gt; v0("abcdefghijklmnop", 16);
  valarray&lt;char&gt; v1("ABCDE", 5);
  const size_t vi[] = { 7, 5, 2, 3, 8 };
  v0[valarray&lt;size_t&gt;(vi, 5)] = v1;
  // v0 == valarray&lt;char&gt;("abCDeBgAEjklmnop", 16)
  —end example]

§ 28.6.2.6 Unary operators

valarray operator+( ) const;
valarray operator-( ) const;
valarray operator-() const;
valarray&lt;bool&gt; operator!( ) const;

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T (bool for operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

Returns: A valarray whose length is size(). Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

§ 28.6.2.7 Compound assignment

valarray& operator*=( const valarray& v);
valarray& operator/=( const valarray& v);
valarray& operator%=( const valarray& v);
valarray& operator+=( const valarray& v);
valarray& operator-=( const valarray& v);
valarray& operator^=( const valarray& v);
valarray& operator&=( const valarray& v);
valarray& operator|=( const valarray& v);
valarray& operator<<=( const valarray& v);
valarray& operator>>=( const valarray& v);

Mandates: The indicated operator can be applied to two operands of type T.

Preconditions: size() == v.size() is true.
The value of an element in the left-hand side of a valarray compound assignment operator does not depend on the value of another element in that left hand side.

Effects: Each of these operators performs the indicated operation on each of the elements of *this and the corresponding element of v.

Returns: *this.
Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.

valarray& operator*=(const T& v);
valarray& operator/=(const T& v);
valarray& operator%=(const T& v);
valarray& operator+=(const T& v);
valarray& operator-=(const T& v);
valarray& operator^=(const T& v);
valarray& operator&=(const T& v);
valarray& operator|=(const T& v);
valarray& operator<<=(const T& v);
valarray& operator>>=(const T& v);

Mandates: The indicated operator can be applied to two operands of type T.

Effects: Each of these operators applies the indicated operation to each element of *this and v.

Returns: *this

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

28.6.2.8 Member functions

void swap(valarray& v) noexcept;

Effects: *this obtains the value of v. v obtains the value of *this.

Complexity: Constant.

size_t size() const;

Returns: The number of elements in the array.

Complexity: Constant time.

T sum() const;

Mandates: operator+= can be applied to operands of type T.

Preconditions: size() > 0 is true.

Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

Preconditions: size() > 0 is true.

Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

Preconditions: size() > 0 is true.

Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

valarray shift(int n) const;

Returns: A valarray of length size(), each of whose elements I is (*this)[I + n] if I + n is non-negative and less than size(), otherwise T().

[Note 1: If element zero is taken as the leftmost element, a positive value of n shifts the elements left n places, with zero fill. — end note]

[Example 1: If the argument has the value −2, the first two elements of the result will be value-initialized (9.4); the third element of the result will be assigned the value of the first element of *this; etc. — end example]
valarray cshift(int n) const;
14

Returns: A valarray of length size() that is a circular shift of *this. If element zero is taken as the
leftmost element, a non-negative value of n shifts the elements circularly left n places and a negative
value of n shifts the elements circularly right −n places.

valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
15

Returns: A valarray whose length is size(). Each element of the returned array is assigned the value
returned by applying the argument function to the corresponding element of *this.

void resize(size_t sz, T c = T());
16

Effects: Changes the length of the *this array to sz and then assigns to each element the value of the
second argument. Resizing invalidates all pointers and references to elements in the array.

28.6.3 valarray non-member operations [valarray.nonmembers]

28.6.3.1 Binary operators [valarray.binary]

template<class T> valarray<T> operator* (const valarray<T>&, const valarray<T>&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T
or which can be unambiguously implicitly converted to T.

Preconditions: The argument arrays have the same length.

Returns: A valarray whose length is equal to the lengths of the argument arrays. Each element of the
returned array is initialized with the result of applying the indicated operator to the corresponding
elements of the argument arrays.

template<class T> valarray<T> operator* (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator* (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator/ (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator% (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator+ (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator- (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator^ (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> operator& (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator| (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator<< (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator>> (const valarray<T>&, const typename valarray<T>::value_type&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.

Returns: A valarray whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

28.6.3.2 Logical operators [valarray.comparison]

Mandates: The indicated operator can be applied to operands of type T and returns a value of type bool or which can be unambiguously implicitly converted to bool.

Preconditions: The two array arguments have the same length.

Returns: A valarray<bool> whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.
Mandates: The indicated operator can be applied to operands of type \( T \) and returns a value of type \( \text{bool} \) or which can be unambiguously implicitly converted to \( \text{bool} \).

Returns: A \( \text{valarray<bool>} \) whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

28.6.3.3 Transcendentals

Mandates: A unique function with the indicated name can be applied (unqualified) to an operand of type \( T \). This function returns a value of type \( T \) or which can be unambiguously implicitly converted to type \( T \).

28.6.4 Class \( \text{slice} \)

28.6.4.1 Overview

namespace std {
  class slice {
    public:
      slice();
      slice(size_t, size_t, size_t);
      slice(const slice&);
      size_t start() const;
      size_t size() const;
      size_t stride() const;

      friend bool operator==(const slice& x, const slice& y);
  };
}

§ 28.6.4.1 1493
The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.\(^{236}\)

### 28.6.4.2 Constructors

```cpp
slice();
slice(size_t start, size_t length, size_t stride);
```

The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

[Example 1: `slice(3, 8, 2)` constructs a slice which selects elements 3, 5, 7, ..., 17 from an array. — end example]

### 28.6.4.3 Access functions

```cpp
size_t start() const;
size_t size() const;
size_t stride() const;
```

- **Returns**: The start, length, or stride specified by a `slice` object.

- **Complexity**: Constant time.

### 28.6.4.4 Operators

```cpp
friend bool operator==(const slice& x, const slice& y);
```

- **Effects**: Equivalent to:
  ```cpp
  return x.start() == y.start() && x.size() == y.size() && x.stride() == y.stride();
  ```

### 28.6.5 Class template `slice_array`

#### 28.6.5.1 Overview

```cpp
namespace std {

  template<class T> class slice_array {

    public:
      using value_type = T;
      
      void operator=(const valarray<T>&) const;
      void operator*(=) (const valarray<T>&) const;
      void operator/= (const valarray<T>&) const;
      void operator%= (const valarray<T>&) const;
      void operator+= (const valarray<T>&) const;
      void operator-= (const valarray<T>&) const;
      void operator^= (const valarray<T>&) const;
      void operator&= (const valarray<T>&) const;
      void operator|= (const valarray<T>&) const;
      void operator<<=(const valarray<T>&) const;
      void operator>>=(const valarray<T>&) const;
      
      slice_array(const slice_array&);
      ~slice_array();
      const slice_array& operator=(const slice_array&);
      void operator=(const T&);
      slice_array() = delete; // as implied by declaring copy constructor above
  };
}
```

1. This template is a helper template used by the `slice` subscript operator

```cpp
slice_array<T> valarray<T>::operator[](slice);
```

---

\(^{236}\) BLAS stands for *Basic Linear Algebra Subprograms*. C++ programs can instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: *A set of Level 3 Basic Linear Algebra Subprograms*; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.
It has reference semantics to a subset of an array specified by a slice object.

[Example 1: The expression \(a[slice(1, 5, 3)] = b\) has the effect of assigning the elements of \(b\) to a slice of the elements in \(a\). For the slice shown, the elements selected from \(a\) are \(1, 4, \ldots, 13\). — end example]

### 28.6.5.2 Assignment

```cpp
void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.5.3 Compound assignment

```cpp
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.5.4 Fill function

```cpp
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.6 The gslife class

#### 28.6.6.1 Overview

```cpp
namespace std {
    class gslife {
        public:
            gslife();
            gslife(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

            size_t start() const;
            valarray<size_t> size() const;
            valarray<size_t> stride() const;
        }
    }
```

1 This class represents a generalized slice out of an array. A `gslife` is defined by a starting offset \(s\), a set of lengths \(l_j\), and a set of strides \(d_j\). The number of lengths shall equal the number of strides.

2 A `gslife` represents a mapping from a set of indices \(i_j\), equal in number to the number of strides, to a single index \(k\). It is useful for building multidimensional array classes using the `valarray` template, which is one-dimensional. The set of one-dimensional index values specified by a `gslife` are

\[
k = s + \sum_j i_j d_j
\]

where the multidimensional indices \(i_j\) range in value from 0 to \(l_j - 1\).

[Example 1: The `gslife` specification

```cpp
    start = 3
    length = {2, 4, 3}
    stride = {19, 4, 1}
```]
yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\[
\begin{align*}
(i_0, & \quad i_1, \quad i_2, \quad k) = \\
(0, & \quad 0, \quad 0, \quad 3), \\
(0, & \quad 0, \quad 1, \quad 4), \\
(0, & \quad 0, \quad 2, \quad 5), \\
(0, & \quad 1, \quad 0, \quad 7), \\
(0, & \quad 1, \quad 1, \quad 8), \\
(0, & \quad 1, \quad 2, \quad 9), \\
(0, & \quad 2, \quad 0, \quad 11), \\
(0, & \quad 2, \quad 1, \quad 12), \\
(0, & \quad 2, \quad 2, \quad 13), \\
(0, & \quad 3, \quad 0, \quad 15), \\
(0, & \quad 3, \quad 1, \quad 16), \\
(0, & \quad 3, \quad 2, \quad 17), \\
(1, & \quad 0, \quad 0, \quad 22), \\
(1, & \quad 0, \quad 1, \quad 23), \\
\ldots \\
(1, & \quad 3, \quad 2, \quad 36)
\end{align*}
\]

That is, the highest-ordered index turns fastest. — end example]

It is possible to have degenerate generalized slices in which an address is repeated.

[Example 2: If the stride parameters in the previous example are changed to \{1, 1, 1\}, the first few elements of the resulting sequence of indices will be

\[
\begin{align*}
(0, & \quad 0, \quad 0, \quad 3), \\
(0, & \quad 0, \quad 1, \quad 4), \\
(0, & \quad 0, \quad 2, \quad 5), \\
(0, & \quad 1, \quad 0, \quad 4), \\
(0, & \quad 1, \quad 1, \quad 5), \\
(0, & \quad 1, \quad 2, \quad 6), \\
\ldots
\end{align*}
\]

— end example]

If a degenerate slice is used as the argument to the non-\texttt{const} version of \texttt{operator[]} (\texttt{const gslice&}), the behavior is undefined.

### 28.6.6.2 Constructors

\texttt{gslice();}
\texttt{gslice(size_t start, const valarray&lt;size_t&gt;k lengths,}
\texttt{const valarray&lt;size_t&gt;k strides);}

The default constructor is equivalent to \texttt{gslice(0, valarray&lt;size_t&gt;(), valarray&lt;size_t&gt;())}.

The constructor with arguments builds a \texttt{gslice} based on a specification of start, lengths, and strides, as explained in the previous subclause.

### 28.6.6.3 Access functions

\texttt{size_t start() const;}
\texttt{valarray&lt;size_t&gt; size() const;}
\texttt{valarray&lt;size_t&gt; stride() const;}

1. Returns: The representation of the start, lengths, or strides specified for the \texttt{gslice}.
2. Complexity: \texttt{start()} is constant time. \texttt{size()} and \texttt{stride()} are linear in the number of strides.
28.6.7 Class template gslice_array [template.gslice.array]

28.6.7.1 Overview [template.gslice.array.overview]

namespace std {
    template<class T> class gslice_array {
